Levulinic Acid and Esters —Sati and Shao-Yuan Ma in the December number of the *Journal of the American Chemical Society* describe a simple procedure for the preparation of levulinic acid from commercial glucose depending on the hydrolysis with boiling hydrochloric acid An intermediate product is oxymethylfurfural A yield of 160 gm per kilo of glucose was obtained, after distillation under 7 mm. pressure, as large glassy crystals, melting at 33° 35° From the acid, seven esters were prepared by direct esterification, they were obtained highly pure and their simple physical constants determined The work was carried out at the National Tsinghua University, Peiping West, China

Hydroxylation and Peroxide Production during Slow Combustion of Ethane —The 'chain theory' of reactions has proved very fertile in accounting for many experimental results otherwise difficult to understand Peroxide formation is believed to play an important rôle in oxidation processes by determining the length of certain reaction chains, if not as the initial stage in the process itself W A Bone with S G Hill (*Proc Roy Soc*, **129** A, 434, 1930) have re examined the slow combustion of ethane to see how far the view might still be held that the process is one of progressive hydroxylation Peroxide formation was observed concomitantly with aldehyde formation, but no evidence was found that peroxide production occurred in the initial stages of the reaction and was not a product of oxidation of the aldehyde While the hydroxylation theory was confirmed, the exact rôle of the peroxides detected must remain uncertain

Absorption of Hydrogen by Nickel —Contrary to what is observed with other metals, and also to the hypotheses of Hallwachs and Hermann, absorption of electrolytic hydrogen by nickel wire is accompanied by increase in the electrical resistance of the metal The results of an investigation into this matter by Franzini, recently described in the *Rendiconti* of the Royal Lombardy Institute of Science and Letters, show also that the temperature coefficient of the resistance is diminished as a result of the absorption of the hydrogen When the gas appears to be uniformly distributed throughout the mass of the metal, the relation between the increase of resistance and the amount of gas absorbed is probably linear, so that $\Delta r/r = cV$, and if V is expressed in volumes of hydrogen absorbed per unit volume of metal, the constant c has the value $0\ 68 \times 10^{-4}$ If the gas is non-uniformly distributed, the increase in resistance is lower than that indicated by the above equation The variation of the temperature coefficient of the resistance is also, in all probability, related linearly to the quantity of absorbed hydrogen

The Origin of Bread Wheats.

By Prof R RUGGLES GATES

AN immense amount of work has been done in recent years in crossing species of cereals and investigating the chromosome behaviour of the hybrids These crosses include not only many cultivated and wild species of wheat, rye, oats and *Ægilops*, but also intergeneric crosses between these four genera, *Triticum*, *Secale*, *Avena*, and *Ægilops* The results have thrown much light on the phylogeny of the bread wheats and their relation to other genera

In all these genera the basal haploid chromosome number is 7, and each genus except rye contains species with $2n$, $4n$, and $6n$ chromosomes It therefore seemed not unlikely that in all three genera the hexaploid condition had been independently reached, through parallel evolution, and that the bread wheats had therefore been derived from crosses between tetraploid and diploid species of wheats, forming triploid sterile hybrids in which chromosome doubling then gave rise to fertile hexaploid forms The recent work has, however, brought much evidence to show that the genera *Ægilops* and *Triticum* are very closely related as regards some of their species, and that *Ægilops cylindrica* is directly or indirectly one of the ancestors of the hexaploid bread wheats or soft wheats This latter view was first put forward by Percival in 1921 on taxonomic grounds, and has now been strongly substantiated by genetical and cytological work, confirmed by various other investigators Various workers now approximate to the view that the A and B sets (of 7 chromosomes each) in *T vulgare* came from the emmer ($4n$) wheats, while the C set has been derived from *Ægilops cylindrica* or its diploid ancestor, and a fourth (D) set from *Æ ovata*

Popova (1923) found that much natural crossing took place in Turkestan, near Tashkent, where the hills were covered with wild *Ægilops cylindrica*, *Æ squarrosa*, and *Æ crassa*, which crossed freely with wheat in the neighbouring fields *Ægilops* species showed numerous parallel variations, as indicated by the variety names, *flavescens*, *rubiginosa*, *albescens*, *ferruginea*, *brunnea*, etc, in different species The wheats also show parallel variations, awned or awnless, smooth or pubescent, ears white, red, brown, etc Also *Æ triuncialis* ($4n$), like the hard ($4n$) wheats, is resistant to rust and has a solid straw, while the other three species of Ægilops mentioned are affected by rust and have a hollow stem, like the soft ($6n$) wheats

The chromosome numbers in more than twenty species of *Ægilops* have now been counted, chiefly by Schiemann (1928) and Sorokina (1928) Among the diploid species ($2n = 14$) are *Æ squarrosa*, *Æ speltoides* and *Æ caudata*, while *Æ triuncialis*, *Æ cylindrica*, and *Æ ventricosa* are tetraploid, and *Æ crassa* and *Æ turcomanica* are hexaploid *Æ crassa* from Turkestan is, however, tetraploid Zhukovsky divided the genus into nine sections In each of these sections the chromosome number is uniform, but the sections do not coincide with chromosome numbers, as is the case in *Triticum* Asia Minor appears to be the centre of distribution of the genus, but evidently the classification of the species into sections has not yet reached a definitive state

Crosses have been made between three subspecies of *Æ triuncialis* ($n = 14$) and two of rye ($n = 7$), by Karpechenko and Sorokina (1929), using the rye as male parent The F_1 grains were mostly shrivelled and the hybrid plants resembled *Ægilops* in the majority of their characters, but the fragility of rachis in rye was dominant The 21 chromosomes in meiosis showed 5-7 bivalents, with the members of each pair end to end Occasionally a trivalent of three chromosomes arranged tandem was seen

Philipchenko (1930) made a study of the development of the ear in different species of wheat, *Ægilops*, and rye He was so impressed with the fact that in *Triticum monococcum* ($n = 7$) the development is different from that of the $4n$ and $6n$ wheats and more like rye, that he proposed to regard it as representing a separate genus, *Monococcum* The systematist's view has been that *T monococcum* (and the wild form *T ægilopoides*) stands apart from other species of *Triticum* To place it in a genus by itself seems, however, rather an extreme action Philipchenko found that the ear development in the hard ($4n$) and soft ($6n$) wheats was very similar, while the differences between *Monococcum*, *Triticum*, and *Secale* appear very early On the contrary, in *Ægilops squarrosa* ($n = 7$), *Æ ovata* ($n = 14$) and *Æ crassa* ($n = 21$) he found no important differences in ear development, from which it is concluded that polyploidy has no influence on ear development in either *Triticum* or *Ægilops*

Vavilov and Jakushkina (1925) reported on a study of *T persicum* Vav and its hybrids with other species of wheat, with *Ægilops* species, and with rye This 'Persian wheat' was obtained at Moscow in 1902 from Haage and Schmidt, who had it from a firm in Moscow in the 'nineties It was a black awned spring wheat, very resistant to mildew, and showing considerable immunity to rust Vavilov in 1916 found in Persia a series of varieties with black ears, pubescent, bearded, of the type of soft wheats, and Zhukovsky discovered in Turkestan a great diversity of varieties of this species *T persicum* is tetraploid and placed by Percival in *T dicoccum*, but Vavilov regards it as forming a link geographically between the Asiatic group, rising to *T vulgare*, and the Afro Mediterranean tetraploid wheats It produces a dirty brown flour without the yellowness of the *durum* wheats, the bread being more like that from rye in appearance but having a peculiar flavour Although tetraploid, it shows a number of characters belonging to the soft wheats It produces fertile hybrids with other $4n$ wheats, but markedly sterile hybrids with $6n$ wheats, and still more with *T monococcum*, as well as in crosses with *Ægilops triuncialis* and rye

In 1914 Tschermak (1929) found in the Greek Theatre at Palermo, and afterwards as a weed in the Appian Way at Rome, the wild *T villosum* or *Secale villosum*, which Bleier showed to be diploid It was used as male in crosses with *T spelta* ($n = 21$), *T durum* ($n = 14$), and especially *T turgidum* ($n = 14$) The latter hybrids were intermediate and mostly sterile A few stronger F_2 plants were obtained from unprotected seeds The strain was more fertile in F_3 and F_4, but showed no segregation This is probably an amphidiploid with $(14 + 7) \times 2 = 42$ chromosomes, but the number has not been counted The first observed case of this kind in wheats will be referred to later

Some of the wheat rye hybrids which have been investigated throw important light on the relationship of the cereals and the general manner in which the hexaploid wheats may have arisen W P. Thompson (1926) studied the cytology of a wheat-rye hybrid The cross was easily made with certain varieties of *T vulgare*, producing a very vigorous F_1, which was not quite sterile Its chromosomes numbered $21 + 7 = 28$ The heterotypic metaphase in meiosis was very irregular There were often one or

two, but rarely three, bivalents. Most of the chromosomes divided in the second division, but many lagging chromosomes formed extra nuclei It was concluded that probably none of the rye chromosomes are homologous with those of the wheats

The experiments on rye-wheat hybrids (*S cereale* × *T vulgare*) which Meister has been making for a number of years at the Saratov station on the Volga have yielded important results Among the practical results has been the production of wheats with valuable rye characters, such as early ripening and winter hardiness Meister also obtained a constant intermediate fertile hybrid in F_3 It has since maintained its type, and the F_8 plants recently examined by Levitsky and Benetzkaia (1929) showed 56 chromosomes It is thus an amphidiploid with $(7+21)\times 2$ chromosomes Meister and others have shown that the F_1 probably do not pollinate themselves, hence there is probably apogamous development of certain F_1 ovules with the somatic chromosome number, this number being doubled in the first mitosis of the egg cell It was found that in the embryo sac of the F_1 the chromosomes do not conjugate but about 28 pass to each pole, so that eggs with 28 chromosomes must be formed The meiosis in the pollen mother cells of the amphidiploid shows 28 bivalent chromosomes, but notwithstanding this balanced condition there are many irregularities from lagging chromosomes and disintegration of certain chromosomes

Perhaps the most striking cases of an amphidiploid hybrid, however, and the first of their kind, were obtained by Tschermak and Bleier (1926) From the crosses *Ægilops ovata* × *T dicoccoides* and *Æ ovata* × *T durum*, constant octoploid forms were derived by chromosome doubling in the F_2, producing plants with normal chromosome pairing in later generations The frequency with which such forms can arise from *Ægilops Triticum* crosses strengthens the view that the hexaploid wheats actually did arise from such a cross between tetraploid (emmer) wheats and a diploid species of *Ægilops* In all the hybrids between *Æ cylindrica* and the 6*n* wheats there are constantly seven close pairs of meiotic chromosomes, from which Percival concludes (1930) that seven of the chromosomes of these wheats have been derived from the tetraploid *Æ cylindrica*

Extensive studies of the chromosome behaviour in many hybrids between *Triticum* and *Ægilops* have also been made by Sax (1924), Jenkins (1929), Aase (1930), Longley and Sands (1930), Bleier (1930), and others Bleier has recently concluded that pairing of the chromosomes in these hybrids depends partly on the varieties chosen and partly on the environment He is less sanguine than some others that the phenomena of pairing will furnish a sufficient key to chromosome homologies in the various species Sax supported the view that the hexaploid wheats came from crosses between emmer and *Ægilops*, based partly on chromosome pairing and partly on the fact that the characters which distinguish the hexaploid from the emmer wheats are all found in *Æ ovata* and *Æ cylindrica*

Another interesting line of evidence of relationships has been obtained by Kagawa (1928, 1929) The volume of the pollen grains in the diploid *Æ speltoides* was compared with that of four tetraploid species In two of the latter (*Æ squarrosa* and *Æ triuncialis*) the volume was approximately double, suggesting that they might be autotetraploids, while in two others (*Æ ovata* and *Æ cylindrica*) it was not In *Æ cylindrica* × *T dicoccum* during meiosis there were sometimes 1-4 end to end pairs, and in *Æ ovata* × *T polonicum* 1 or 2 such pairs Occasionally the chromosomes in such a pair were of unequal size But Kagawa's most interesting work was in carefully comparing the types of the somatic chromosomes in various species of *Triticum*, *Ægilops*, and *Hordeum*. The chromosome pairs in a species frequently show constant differences both in length and in the position of constrictions or spindle fibre attachments By these methods it was found that *T monococcum* has three long pairs of chromosomes (two of which have a single constriction and the third two constrictions), the other four pairs being progressively shorter, with characteristically placed constrictions *T polonicum* had four similar pairs and others that were different By such comparisons of the chromosome sets in different species it was concluded that in *T polonicum*, *T dicoccum*, and *T vulgare* most of the chromosome types were represented by a single pair in each cell, and similarly that the tetraploid *Ægilops cylindrica* could not have arisen from the doubling of the chromosomes in *Æ speltoides* While this work is doubtless subject to some revision, it seems to show that autopolyploidy has seldom occurred in these genera, but that higher chromosome numbers have usually appeared following crossing

Watkins, in a series of papers (1928), has made an intensive study of crosses between *T turgidum* (4*n*) and *T vulgare* (6*n*) Among his conclusions may be mentioned that the differences between the conspicuous hexaploid types *vulgare*, speltoid, and *spelta* were due to three factors, *k*, *K*, and *Ks*, which were either multiple allelomorphs producing different degrees of keeled glumes (the most conspicuous difference between *turgidum* and *vulgare*) from the round-glumed *vulgare*, or more probably three groups of completely linked factors This view is supported by the fact that these three factors or factor groups all show the same linkage value with the factor for awns The factor *Ks* in *dicoccum* is moreover identified with *Ks* in *spelta*, while similar factors *K'K'* are believed to be carried by the extra chromosome sets of *spelta* Thus *turgidum* and *durum* are given the formula *KK*, and *vulgare* (*kk*)*K'K'* By study of the cytology of reciprocal back-crosses of the F_1 *turgidum-vulgare* hybrids with both parents, it was found that 14 *turgidum* chromosomes pair with 14 of the *vulgare* The conclusion was reached that the 14 chromosome pollen from the back crosses carries mainly *turgidum* characters, while the pollen with 17 21 chromosomes carries mainly *vulgare* characters The results did not disclose many factor differences between the 14 *turgidum* chromosomes and the 14 *vulgare* chromosomes with which they pair, leading to the suggestion that a simple polyploid relationship exists between these two species

Huskins (1930) finds irregularity in the meiosis of *T spelta* and *T vulgare*, and on this basis extends Winge's hypothesis of the origin of speltoid wheats through irregular distribution of certain chromosome pairs in the reduction division Thompson and Robertson (1930) have also found in hybrids *vulgare* × *spelta* and *vulgare* × *compactum* a considerable proportion of pollen mother cells with one or a few lagging univalent chromosomes, such cells being much less frequent in the pure species Similar results are obtained among the tetraploid wheats Such phenomena indicate complete homology between chromosomes which fail to pair Thompson has also shown that in various hybrids between species with different chromosome numbers there is disharmony between the embryo and the endosperm with its additional set of maternal chromosomes, thus leading to differences in reciprocal crosses

Percival (1930) has studied 33 hybrids between four tetraploid *Ægilops* species (*ovata*, *cylindrica*, *triuncialis*, and *ventricosa*) and various 2*n*, 4*n*, and 6*n* wheats, as well as hybrids between the four *Ægilops* species themselves In hybrids between *Ægilops* and

wheats he finds a certain number of bivalent chromosomes, which are all telosynaptic or end-to-end In crosses between *Æ cylindrica* and the 6n wheats, however, he always finds constantly 7 parasyndetic bivalents formed from the end to end arrangement by the chromosomes swinging round to lie side by side This, as well as the characters of *cylindrica*, point to the presence of 7 *cylindrica* chromosomes in the hexaploid wheats Hence telosynaptic pairing is regarded as evidence of a less complete homology or a more distant relationship between the members of a pair than is parasynapsis

The hybrid *Æ cylindrica* × *Æ ventricosa* is sterile, but its characters show remarkable resemblance to those of *T spelta* In meiosis there are 5 7 bivalent chromosomes, chiefly parasyndetic but some telosyndetic, indicating that one set of chromosomes are homologous in the two species The two types of pairing are also described in various species hybrids by Aase Percival also considers *T dicoccoides* (4n) to be an autopolyploid of *T ægilopoides*, and concludes that the emmer wheats are probably autopolyploids from the Einkorn wheats These conclusions, however, require further evidence

Nishiyama (1930) has described similar conditions in crosses of *Avena* species *A fatua* ($n = 21$) × *A sativa* ($n = 21$) gives a hybrid with 21 parasyndetic bivalents in meiosis, leading Percival to conclude that cultivated oats was derived from the wild *fatua*, while *A barbata* ($n = 7$) × *A sterilis* gives telosyndetic pairs

Watkins (1930) has just published an extensive critique of all the work on wheat (*Jour Genet*, vol 23, No 2), in which he points out difficulties with the theory of cumulative factors for size inheritance as applied to wheats, and shows that the chromosome behaviour of hybrid cereals requires further study While the details therefore remain uncertain, there is evidence for concluding that the origin of the hexaploid wheats has involved interspecific and intergeneric crossing, with allopolyploidy and probably also autopolyploidy, combined with the occurrence of numerous parallel unit mutations

A recent study of the related grass genus *Agropyron* by Peto (*Can Jour Research*, vol 3, p 428) again shows 2n, 4n, and 6n species ($n = 7$), with evidence of natural hybridisation between species having the same or different chromosome numbers This condition is probably very similar to that under which the wheats evolved, except that the hexaploid wheats may have arisen entirely under conditions of cultivation

Upper Atmosphere over India

THE inexpensive type of apparatus for obtaining readings of pressure and temperature at great heights in the upper atmosphere which was invented by the late W H Dines in 1907 has been employed in many countries It has been used with one minor modification at Agra (*Gerlands Beiträge zur Geophysik*, vol 25 (1930), pp 266-278, by G Chatterjee and N K Sur)

In Dines's apparatus the graph of each record, temperature and pressure being the ordinates and abscissæ, is traced by a sharp non rusting steel point on a silvered copper plate little larger than a postage stamp, the motion due to variations of pressure being provided by a small aneroid box and those due to change of temperature by the expansion and contraction of a rod of German silver Difficulty was experienced at Agra in obtaining a continuous scratch on the recording plate, especially when the sounding balloon carried the instrument into the stratosphere, which is there reached at a higher level than over the British Isles, and is in consequence much colder It was found that the substitution of a deposit of colloidal graphite on glass, for the silver surface, overcame this tendency, and allowed very sharp records to be obtained with only slight pen pressure

Owing to the rapidity with which rubber balloons perish in India, Vulpro tissue balloons (see NATURE, vol 124, p 793, 1929) were substituted for them in 1926, since then balloons have often risen as high as the stratosphere, and the number of observations obtained permits of a fairly detailed account of the seasonal changes of temperature between the level of the ground and a height of 20 km

The monsoon season in India (June to September) was found to be decidedly the hottest up to nearly 14 km, and at this season the lapse rate of temperature is higher between 12 km and 15 km than lower down, a state of affairs believed to be due to a difference of origin of the air above and below the average level of the cirrus clouds (12 km) The base of the stratosphere (the 'tropo pause') appears to be found at an average height of about 16 km or 17 km at all seasons, but its mean temperature has an annual variation with a minimum of 192° A at about the end of the rainy season The lowest value obtained at Agra so far is 181° A at a height of 16 5 km on Oct 4, 1928, which equals the lowest yet found —at a slightly higher level—over Batavia in 1923, which for long was regarded as the lowest atmospheric temperature observed anywhere in the world

'Sea Trout' or 'Bull Trout'?

THE brown trout and the sea trout, possibly members of one plastic species, have been the cause of much controversy Living under widely varying conditions and possessing very different habits, they show differences in appearance which have given ground for much 'splitting' in the past Furthermore, because they have come much under the eye of observant anglers, many without the knowledge of a trained biologist, who himself is always in difficulties when deciding where a 'species' ends and where it begins, it is natural that the popular accounts of these fish have shown very divergent opinions That they are specifically indistinguishable is perhaps the general consensus of opinion at the present day, but there has still been a certain amount of indecision as to where exactly to place the so called 'bull trout' of the Tweed and other rivers

A critical examination of the sea trout of the river Tweed * comes therefore as a welcome addition to our knowledge of this interesting species Mr G H Nall, of the Scottish Fishery Board, has shown that the sea trout of the Tweed exhibit a marked difference from those of many other Scottish rivers in the great rapidity of their growth during sea life As an example, the average weight of a fish in its third sea summer for the Tweed is 7 lb 7 oz, as against 3 lb 5 oz for the Howmore, 2 lb 13 oz for the Ailort, 2 lb 6 oz for the Forth, and 2 lb 3 oz for the Spey Similarly, for fish in their fifth sea summer the average weight for the Tweed is 12¼ lb as against the highest of 6 lb 7 oz for the Howmore amongst the above four rivers

* Fisheries, Scotland, Salmon Fish, 1929, No 5 Sea Trout of the River Tweed By G Herbert Nall (London H M Stationery Office, 1930) 3s 6d net

Coincident with this rapidity of growth is a short span of life, and consequently few spawning operations. There is an indication that the Tweed sea trout travel very far afield during their sojourn in the sea, which may account for their great growth; marked fish have been recovered from the South Esk, from off the Norfolk coast, off the Dutch coast, and off the Jutland coast of Denmark, though the numbers of recaptures from each place so far only amount to single figures.

Owing to the divergent characters of the spawning grounds in a river with so large a number of tributaries as the Tweed, and since the fish may stay close to their home neighbourhood or range very far afield during their sea life, it is possible that various types of fish may become apparent. As a result of his examinations, Mr. Nall comes to the opinion that "there is no evidence to justify the old belief that the Tweed has two or more distinct races of sea trout". He considers, however, that the sea trout of this river undoubtedly do form a well marked local race, similar to that found in Northumbrian rivers to the south; but that this does not warrant them being considered a different species as the name *Salmo eriox* would imply, nor is the name 'bull trout' applicable, since it is a term applied in different districts to very different types of fish and is therefore misleading.

F. S. R.

University and Educational Intelligence

BIRMINGHAM.—In his annual report to the Court of Governors, the Vice-Chancellor, Sir Charles Grant Robertson, announces that during the past session the upward tendency in numbers of students at the University was maintained. The number of new entries for the present session, however, shows a slight falling off. Sir Charles Robertson is of opinion that while the depression of trade may have little effect on the number of students entering the University, it has marked and far-reaching effects on the student who has, in consequence, perhaps £10 a year less to spend on the amenities which mean so much in a university education, as distinguished from mere university instruction. Considering that 49 per cent of the students hold scholarships or have assistance in meeting the expenses of their university careers, and that about 53 per cent began their education in elementary schools, it will be understood that such a curtailment of spending power affects many. "Hence particularly in hard times, it is wise as far as possible to remember that expenditure on Library, Refectories, and Halls of Residence have their educational values. . . . In *principle*, the application of university income to promote activities or create opportunities, so as to secure that a university education, and not merely university instruction, is provided, is as justifiable as the allocation of that income to scholarships, exhibitions, lecture rooms, or apparatus." Reference is made to the increase in the Government grant to the University, and it is suggested that about half of this should go to increase the salaries of professors. The voluntary medical examination of intending women students has proved so satisfactory that all the women avail themselves of it, and it is suggested that a similar opportunity should be given to the men students.

Prof. S. W. J. Smith has been appointed to represent the University at the Clerk Maxwell Centenary at Cambridge in October.

CAMBRIDGE.—The Appointments Committee of the Faculty of Biology 'A' has appointed Mr. W. B. R. King, of Magdalene College, to be University lecturer in geology. The Faculty Board of Biology 'A' has appointed Dr. H. Godwin, Mr. J. Gray, of King's College, Dr. H. H. Thomas, and Dr. F. F. Blackman, of St. John's College, to be members of the Botanic Gardens Syndicate.

LONDON.—The London County Council has informed the University that the Council's block maintenance grant to the University in each of the four academic years, 1931–32 to 1934–35, will be £125,000. This is an increase of £20,000 on the Council's grant for the current year and of £44,000 on that for 1929–30.

ST. ANDREWS.—Dr. D. F. Cappell, lecturer in pathological histology in the University of Glasgow, has been appointed professor of pathology in the University of St. Andrews in succession to Prof. Sutherland, who retired at the end of last academical year. Dr. Cappell graduated in the University of Glasgow as M.B., Ch.B., in 1921, and has since been engaged in teaching and research work in pathology in the University of Glasgow.

WALES.—Five fellowships, each of the annual value of £200 and tenable for two years, are being offered to graduates of the University of Wales. Applications should be sent, by, at latest, June 1, to the Registrar, University Registry, Cathays Park, Cardiff.

AN election to Beit fellowships for scientific research will take place in July. Only candidates less than twenty-five years of age are eligible. The latest date for the receipt of applications (which should be sent to the Rector, Imperial College of Science, South Kensington, S.W.7) is April 14.

THE following scholarships are being offered by King's College of Household and Social Science: a 'Carl Meyer', value £80 a year, tenable for three years, and a 'Minor College', value £40 a year, tenable for three years. Particulars can be had from the Secretary of the College, Campden Hill Road, W.8.

TATE and Morgan scholarships for the session 1931–1932 are being offered by Battersea Polytechnic, and the examinations for them will be held on June 9 and following days. The scholarships will be tenable for two or three years. The yearly value of each will be from £20 to £30, with free tuition. Particulars are obtainable from the Principal. Applications must be made, at the latest, by April 18.

NOTICE is given by the Faraday House Electrical Engineering College that examinations for the Faraday and Maxwell scholarships will be held on Mar. 31, April 1 and 2. The annual value of the former scholarship is 80 guineas and that of the latter 60 guineas. The scholarships are tenable for two years in the college and one year in works. Particulars are obtainable from the Registrar of the College, 62 Southampton Row, W.C.1.

THE Board of Education is again prepared to receive applications for Full Time Studentships from teachers desiring financial assistance in order to attend approved full time courses of advanced study at universities or other institutions at home or abroad. The amount of grant is fixed by the Board and cannot exceed £100 for an academic year. The course proposed, if academic, should be of post-graduate type, but the Board is prepared to consider also proposals involving travel or the practical study of industrial conditions connected with the teaching of technical subjects. Applications for the year 1931–32 should be made before May 31. Further information and application forms can be obtained from the Board of Education, Whitehall, London, S.W.1.

Birthdays and Research Centres

Feb 28, 1858.—Mr J SWINBURNE, F R S, past president of the Institution of Electrical Engineers and of the Faraday Society

My present investigations are on the behaviour of the watch balance and the photography in relief of micro scopic objects

Further research is little more than intellectual exercise, since *humanity is too ignorant to utilise it* well because natural science is immeasurably ahead of other branches of knowledge Human happiness involves first a science of sociology, and this is scarcely begun People do not know it exists, and think important questions can be settled without study On social questions people are not merely ignorant, they are saturated with wrong ideas and prejudices and are full of negative knowledge The history of early Greece is vague, but, we may take it, applied sociology, in the form of modern governments, is more than two thousand seven hundred years behind ap plied natural science

Mar 2, 1870—SIR FREDERICK W KEEBLE, C B E, F R S, controller of agricultural research, Imperial Chemical Industries, Ltd, formerly Sherardian professor of botany in the University of Oxford

The investigations on which I am now engaged are twofold in object The chief series, which is being carried out in co operation with the agricultural research staff of Imperial Chemical Industries, Ltd, is concerned with the improvement of arable and grass land and the more profitable utilisation of pastures and meadows, a subject which, apart from its scientific interest, has a far reaching importance in relation to the welfare of Great Britain and the Dominions of the Empire

The second subject is the chemical and other means whereby the plant body is integrated so that, made up of similar parts having no apparent nervous ties, the organism nevertheless behaves continuously as a whole, co ordinating the activities of the several parts in what appears to be the general interest of the plant itself

Mar 7, 1869—Prof ERNST COHEN, For Mem R S, professor of physical chemistry, University of Utrecht

The investigations I have carried out during these last few years with my collaborators, Drs Moesveld, Helderman, Bruins, Douwes Dekker, van Dobben burgh, Kooy, and Bredée, have shown that the physical and physico-chemical constants of *chemically pure* solid substances hitherto recognised are values which refer very often, if not always, to metastable mixtures, which contain two or more modifications of those substances in unknown proportions These substances are *physically impure* As a consequence of this fact, errors of 5, 10, 100, 200 and more per cent in the physical and physico chemical constants of such substances may occur We are now studying methods whereby the *chemically* and *physically* pure stable and metastable modifications may be prepared and their physical and physico-chemical properties ascertained

Societies and Academies.

LONDON

Royal Society, Feb 19—**A J Allmand and L J Burrage** The discontinuous nature of the process of sorption of gases and vapours by porous solids A summary is given of results obtained either at low pressures or by a new 'retentivity' technique, indicating the presence of discontinuities in the adsorption isothermals and isosteres of vapours on charcoal The technique is described of a simple static method for the determination of adsorption isothermals, which permits of the detailed examination of a limited pressure range being rapidly carried out Breaks in the isothermals were found in all cases Measurements with silica gel and with benzene, carbon tetrachloride, and water also showed discontinuities, rudimentary or slight in the first two cases, but very pronounced with water A view of the mechanism of the adsorption process is outlined which has features in common with Polanyi's modified theory and with recent suggestions of Semenoff Distinctions are made between the behaviour (*a*) of activated charcoal and of silica gel and (*b*) of water (molecules natural dipoles) and of carbon tetrachloride (molecules without dipole moment)—**L N G Filon and F C Harris** The photo elastic dispersion of vitreous silica Double refraction was measured for a series of well determined wave lengths, the load on the specimen remaining unaltered throughout each set of observations The results show (1) that the law of photo elastic dispersion in silica varies slightly with the load applied, so that the usual assumption that the double refraction is proportional to the stress cannot in this case be exactly true, (2) that the curve of photo elastic dispersion shows marked and highly localised oscillations, (3) that these oscillations are very probably due to some natural periods of the molecules—**C G Darwin** Examples of the uncertainty principle Observations with electrometers and magneto meters conform to the uncertainty principle of Heisenberg—**G B Deodhar** Some investigations in Röntgen spectra (1) The $K\alpha$ and $K\beta$ groups of the elements silicon, phosphorus, sulphur and chlorine have been studied—(2) A large number of sulphur compounds have been examined, and it is found that considerable changes in the relative intensities of the β_1 and β_x lines take place from substance to substance—(3) The fine structure of the K-edge of silica is recorded and measured by using quartz as the analysing and absorbing substance The observed fine structure may result from the ejected K-electron stopping in one of the possible virtual electron orbits in the SiO_2 molecule, as has been suggested in the investigation of the spectra of sulphur compounds

Physical Society, Jan 16—**T L Ibbs** The influence of low temperatures on the thermal diffusion effect Measurements of thermal diffusion on the following gas mixtures at temperatures between 15° C and −190° C are described helium neon, hydrogen-neon, helium argon, neon argon, helium nitrogen There is a general tendency for k_t to decrease at low temperatures It is found, however, that for the pairs of gases helium neon and hydrogen-neon the change in k_t between 15° C and −190° C is small Chapman's theory is used to deduce approximate values of the laws of repulsive force operating between unlike molecules during collisions At low temperatures, molecules tend to become 'softer' and their behaviour is less like that of rigid elastic spheres The 'hardest' molecules appear to show the smallest variation in k_t The influence of helium in this respect on the value of k_t for a mixture is clearly shown

Linnean Society, Feb 19 —**V S Summerhayes** The angiospermic flora of the Seychelles Archipelago The angiosperms of the Seychelles number altogether 479 species, of which, after deducting 247 weeds and escapes from cultivation, 232 remain as indigenous These include 7 marine and 54 littoral species, the remaining 171 being inland species Neither the marine nor the littoral species afford much indication of the origin of the flora as a whole The fact that the dominant forest trees are mostly of Asiatic affinity strengthens the indications that the flora of the Archipelago is chiefly Asiatic in origin The total of 171 inland indigenous species is very small, considering the area of the group (160 square miles) This is probably due to the intense competition between the species of an originally much larger flora, consequent on the gradual reduction in area of a land mass of 20,000 square miles to the present islands It is suggested that this took place relatively recently, since there is little evidence of specific segregation as between the floras of different islands or island groups

DUBLIN

Royal Dublin Society, Jan 27 —**A R G Atkins** and **H H Poole** Photoelectric measurements of illumination in relation to plant distribution (4) Changes in the colour composition of daylight in the open and in shaded situations Campbell's thin film cæsium on silver vacuum cell was used with various coloured filters, the colour transmission curves of which were obtained by means of a monochromatic illuminator, and a Moll vacuum thermopile The photoelectric current was measured in the field by J H J Poole's neon lamp method The relative intensities of the various colours in shaded sites were compared with those found for the diffuse light in the open The measurements clearly show the great relative abundance of green and of deep red light in woods, and the scarcity of blue light This change of spectral distribution seems to follow closely the colour transmission curve for chlorophyll Measurements were also made of the relative colour intensities of sunlight and diffuse daylight in the open, under various conditions

PARIS

Academy of Sciences, Dec 29 —**E Goursat** Some integrable forms of a Monge equation —**H Deslandres** Simple relations of molecular spectra with the structure of the molecule Since 1919 the author has pointed out that the frequency $d_1 = 1062\ 5$ is a fundamental one in molecular and atomic spectra In the present paper new data are given in confirmation, including some data based on the Raman spectrum —**L Blaringhem** and **M Chopin** The regularity of the surface tensions of the fresh latex of *Euphorbia Lathyris* In an earlier communication, a description was given of an instrument capable of measuring the surface tension of very small quantities of a colloidal liquid The application of this apparatus to the measurement of the surface tension of the latex of *Euphorbia Lathyris* shows that the surface tensions of this latex are unexpectedly constant and might serve to characterise the type Latices from other plants gave different figures —**Gabriel Bertrand** and **Mme Y Beauzemont** The proportion of zinc in the liver of the rat in course of growth. The percentage of zinc is highest in the liver of the new born rat, gradually falling to about one-third in the adult rat —**Ch Achard** and **M Piettre** The mucin of articular fluids Mucin from the synovial fluid is characterised by its high viscosity and percentage of sulphur (0 7 per cent) —**C de la Vallée Poussin** The conformal representation of multiply connex-plane areas —**C Gutton** and **G Beauvais** The reflection of electromagnetic waves. A repetition of Garbasso's experiment on the reflection of Hertzian waves by resonators with very short wave-lengths (17 cm) —**E Mathias** The confusion between the effects of lightning proper with those of fulminating material The author distinguishes between the effects of lightning, a current of electricity, and those of the explosive compound (a chemical substance) produced by the flash —Henri Lagatu was elected *correspondant* for the Section of Rural Economy in succession to the late M Godlewski —**Léon Pomey** A problem put by Chasles (The generalisation of Pascal's theorem)—**V Chepeleff** and **M Lavrentieff** Conformal representation —**Henri Milloux** A general property of integral functions of infinite order —**A Buhl** Dynamical considerations connected with wave geometry —**Kao Lou** A map of the sky in the Paris National Library This has been regarded as a Chinese map , but the author gives reasons against this view The date of the map is probably A D 1711 —**J Ph Lagrula** The homographic formulæ of verticity and their direct development —**Th V Jonescu** and **C Mihul** The dielectric constant and conductivity of ionised gases —**Jean Louis Destouches** The theoretical interpretation of the Davis Barnes effect This explanation is based on a formula given by Stireckelberg and Morse —**J J Trillat** The phenomena of transformations of the nitrocellulose network Their generality in cellulose compounds —**J Peltier** Research on the flaws and vibrations of ferro-magnetic test pieces A modification of the method previously described, in which an amplifying arrangement and loud-speaker replace the galvanometer —**Ch Dévé** A projector of alignment —**George F Jaubert** A reinforced pseudo liquid colloidal diaphragm, intended for the electrolytic decomposition of water The diaphragm is formed of metal gauze, with a colloid such as magnesium and calcium silicate (colloidal asbestos) deposited from suspension in a caustic potash solution by the action of an electric current The layer thus formed offers no resistance to the passage of the current or the electrolyte, but is quite impermeable to the gases (hydrogen and oxygen) With cells taking up to 5000 amperes the hydrogen obtained is 100 per cent pure, but the oxygen contains about 0 5 per cent hydrogen —**La Goldstein** Atoms of recoil in gaseous media —**R Charonnat** Researches on the rôle of water in salts the *aquo* combinations of the ruthenium IV ammines —**G Darzens** and **A Lévy** Dimethylallylbenzylacetic acid and isopropylbenzyl valerolactone —**L S Glichitch** A new monocyclic sesquiterpene alcohol, fokienol This new alcohol has been obtained from the essential oil of Pe-Mou, *Fokienia Hodginsii*, and was obtained pure through its formate Dehydrated by the method of L Ruzicka and J Meyer, fokienol gives 1 6 dimethyl 4-isopropyl naphthalene (cadaline) —**J F Durand** and **Lai-Wai Hsun** The action of the hexahalogen benzenes on mixed organo magnesium compounds Hexamethylbenzene was obtained by the action of methylmagnesium iodide in large excess upon hexabrombenzene hexaphenylbenzene was prepared similarly from phenylmagnesium bromide —**P Fallot** and **M Blumenthal** The tectonic interpretation of the north west of the Spanish Rif —**P Rougerie** The daily variation of the earth currents recorded at the Parc Saint-Maur Observatory —**F. Bordas** The rain of mud of November 27, 1930 Analyses prove the similarity of composition between the dusts collected at Paris and in the south of France The origin of the dust is doubtful, but northern Africa appears probable —**Jean Piveteau** : The distribution of Teleost fishes in large natural groups —**André**

Meunier: Researches on the variations in the coloration of plants in the course of drying The arbutoside arbutine is the chromogen of *Orobus niger* —Emile F. Terroine, R Bonnet, P Danmanville, and Mlle. G Mourot The excretion of creative substances as a function of the endogenous nitrogenous expenditure —P Chevey · An attempt to apply the method of observation of the scales to the study of the growth of the fish in the Grand Lac du Cambodge and of Tonlé Sap —Jean Loiseleur The properties of the biochemical constituents, especially proteins, in anhydrous solutions —A Blanchetière The fermentative hydrolysis of gelatine in its relations with the formation of the diacipiperazines —P Delanoë The rôle of the porcupine as a reservoir of the virus of the Moroccan spirochæte, *Sp hispanicum* var *morocanum*

Diary of Societies

FRIDAY, FEBRUARY 27

INSTITUTION OF ELECTRICAL ENGINEERS (West Wales (Swansea) Sub-Centre) (at Electricity Offices, Swansea), at 6.—B Leggett The Medical and Surgical Applications of Electricity

NORTH EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (at Mining Institute, Newcastle upon Tyne), at 6.—Dr J Montgomerie Some Notes on Motor Engine Seatings.

INSTITUTION OF STRUCTURAL ENGINEERS (at Chamber of Commerce, Birmingham), at 6 30 —A Lakeman The Construction of an American Factory

MANCHESTER LITERARY AND PHILOSOPHICAL SOCIETY (Chemical Section), at 7

OIL AND COLOUR CHEMISTS' ASSOCIATION (Manchester Section) (jointly with Institution of Rubber Industry) (at Milton Hall, Manchester), at 7.—G. F Thompson and E V Bratby Colours used in the Rubber Industry.

WEST CUMBERLAND SOCIETY OF CHEMISTS (at Workington), at 7 —Dr. G B Slottman Fuel Economy in Iron and Steel

SOCIETY OF CHEMICAL INDUSTRY (South Wales Section) (at Cardiff Technical College), at 7 15.—A Watson The Work of the Building Research Station

BLACKBURN TEXTILE SOCIETY (at Blackburn Technical College), at 7 30 — J H Strong Some Modern Tendencies in Cotton Manufacturing

SOCIETY OF CHEMICAL INDUSTRY (Newcastle-upon Tyne Section) (at Armstrong College, Newcastle upon Tyne), at 7 30 —Dr B Moore Fused Silica in Industry

JUNIOR INSTITUTION OF ENGINEERS, at 7 30 —W A Tookey Oil Engines for the Maritime Fishing Industry

ROYAL SOCIETY OF MEDICINE (Epidemiology and State Medicine Section), at 8 —Dr P Manson Bahr The Epidemiology of Human Trypanosomiasis

ROYAL INSTITUTION OF GREAT BRITAIN, at 9 —Sir Francis Younghusband: The Re-Birth of India.

ROYAL AERONAUTICAL SOCIETY (Hull and Leeds Branch).—H Sutton Aircraft Light Alloys

SOCIETY OF CHEMICAL INDUSTRY (South Wales Section) (jointly with Institute of Chemistry) (at Thomas Café, Swansea) —Dr A J Amour The Pathology of some Industrial Poisons

INSTITUTION OF ELECTRICAL ENGINEERS (at Armstrong College, Newcastle on Tyne) —F J Baldwin Overhead Line Work—More Especially in Connexion with the Grid (Students Lecture).

SATURDAY, FEBRUARY 28

MATHEMATICAL ASSOCIATION (at Bedford College), at 3 —W J Dobbs The Correlation of Trigonometry and Geometry in Elementary School Mathematics

ROYAL INSTITUTION OF GREAT BRITAIN, at 3 —J Stephens A Poetry Recital

INSTITUTE OF BRITISH FOUNDRYMEN (East Midlands Branch) (at Technical College Derby), at 6 —F C Edwards Testing Castings

INSTITUTE OF BRITISH FOUNDRYMEN (Newcastle-on Tyne and District Branch) (at Neville Hall, Newcastle on Tyne), at 6 15 —C E Pearson The Deterioration of Grey Cast Iron on Repeated or Prolonged Heating

INSTITUTE OF BRITISH FOUNDRYMEN (Wales and Monmouth Branch) (at Merchant Venturers Technical College, Bristol), at 6 30 —W Jackson Interesting Moulding Jobs

HULL ASSOCIATION OF ENGINEERS (at Municipal Technical College Hull), at 7 15 —Capt. A E Butterfield Development of Unattended Navigation Lights

MONDAY, MARCH 2

ROYAL SOCIETY, EDINBURGH at 4 30 —Dr Baini Prashad Some Noteworthy Examples of Parallel Evolution in the Molluscan Faunas of South Eastern Asia and South America - Prof H Briggs The Classification and Development of the Carbonaceous Minerals of Organic Origin —*To be read by title only* - H V Lowry Properties of the Function Ein (x).—Dr A C Aitken and A Oppenheim On Charlier's New Form of the Frequency Function

ROYAL INSTITUTION OF GREAT BRITAIN, at 5 —General Meeting

SOCIETY OF ENGINEERS (at Geological Society), at 6 —E Kilburn Scott The Career of Matthew Murray

INSTITUTION OF ELECTRICAL ENGINEERS (Informal Meeting), at 7 —T C Gilbert and others Discussion on Earthing *versus* Artificial Earthing

INSTITUTION OF ELECTRICAL ENGINEERS (South Midland Centre) (at Birmingham University) at 7 —S W Melson A N Arman, and W Bibby Surge Investigations on Overhead Line and Cable Systems

INSTITUTION OF ELECTRICAL ENGINEERS (Western Centre) (at Bristol) at 7 —J W Rissik and H Rissik Heavy Duty Rectifiers and their Application to Traction Substations

SOCIETY OF CHEMICAL INDUSTRY (London Section) (at Chemical Society), at 8 —W H Gray Dr J W Trevan, and Miss H W Bainbridge The Chemotherapy of Antimony

ROYAL INSTITUTE OF BRITISH ARCHITECTS, at 8 30 —Presentation of the Royal Gold Medal

BRITISH PSYCHOLOGICAL SOCIETY (Education Section) (at London Day Training College), at 8 30 —Miss M N Searl Some Contrasted Aspects of Psycho Analysis and Education

HUNTERIAN SOCIETY OF LONDON (at Apothecaries Hall) at 9 —A E M Woolf The Surgical Aspects of Diverticulitis (Hunterian Oration).

TUESDAY, MARCH 3

ROYAL COLLEGE OF PHYSICIANS OF LONDON at 5 —Surg Capt. S. F Dudley Some Lessons of the Distribution of Infectious Disease in the Royal Navy (Milroy Lectures) (2).

ROYAL INSTITUTION OF GREAT BRITAIN at 5 15 —Sir William Bragg Recent Experimental Physics (4) Adhesion (2)

ROYAL SOCIETY OF MEDICINE (Orthopædics Section), at 5 30 —Clinical Meeting

ZOOLOGICAL SOCIETY OF LONDON, at 5 30 —S Zuckerman The Menstrual Cycle in the Primates III The Alleged Breeding Season of the Primates, with special reference to the Chacma Baboon (*Papio porcarius*).—Major S. S Flower Contributions to our Knowledge of the Duration of Life in Vertebrate Animals V Mammals —Malcolm A Smith Description of a New Genus of Sea Snakes from the Coast of Australia, with a Note on the Structures providing for Complete Closure of the Mouth in Aquatic Snakes —E Le G Troughton The Occurrence of a Male and Female *Grampus griseus* (Delphinidæ) at Sydney, New South Wales.—Dr E Schwarz A Revision of the Genera and Species of Madagascar Lemuridæ —Dr W J Dakin The Osmotic Concentration of the Blood of *Callorhynchus millii* and *Epiceratodus forsteri* and the Significance of the Physico-chemical Condition of the Blood in regard to the Systematic Position of the Holocephali and the Dipnoi —Rev E. J Pearce Report on the Haliplidæ (Coleoptera) Mr Omer Cooper's Investigation of the Abyssinian Freshwaters (Hugh Scott Expedition).

INSTITUTION OF ELECTRICAL ENGINEERS (London Students Section), at 6.15 —C C Paterson Address.

EUGENICS SOCIETY (at 20 Grosvenor Gardens, S.W 1), at 6 30 and 8 30 — Study Circle

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 7 —W L Shand The Italian Riviera (Lecture).

INSTITUTION OF AUTOMOBILE ENGINEERS (at Royal Society of Arts), at 7 45 —L A Legros Standardisation

LEICESTER LITERARY AND PHILOSOPHICAL SOCIETY (Chemistry Section) (jointly with Leicester University College Biological Society) (at University College, Leicester), at 8.—Prof A. R. Ling Polysaccharides

INSTITUTION OF ELECTRICAL ENGINEERS (East Midland Sub-Centre) (at College of Technology Leicester).—H G Taylor Phenomena connected with the Collection of Current from Commutators and Slip Rings.

WEDNESDAY, MARCH 4

GEOLOGICAL SOCIETY OF LONDON, at 5 30 —W A Macfadyen The Geology of British Somaliland (Lecture)

INSTITUTION OF ELECTRICAL ENGINEERS (Wireless Section), at 6 —C E Horton The Practical Correction of a Wireless Direction Finder for Deviations Due to the Metal Work of a Ship

INSTITUTION OF HEATING AND VENTILATING ENGINEERS (at 20 Hart Street W C 1), at 7 —W E Fretwell Public Baths and Wash Houses *Engineering Equipment and Data*

INSTITUTE OF METALS (London Local Section) (at 83 Pall Mall) at 7 30 —Dr C J Smithells Gases in Metals

SOCIETY OF PUBLIC ANALYSTS AND OTHER ANALYTICAL CHEMISTS (Annual General Meeting) (at Chemical Society), at 8 —Presidential Address —*Papers to be read by title* —H Ikuta The Investigation of Japanese Beeswax. —J Bamford The Deniges Oliver Test for Morphine.

ROYAL SOCIETY OF ARTS at 8 —W G Raffé Training for Advertising and Commercial Art

ROYAL SOCIETY OF MEDICINE (Surgery Section) at 8 30 —D C L Fitzwilliams Fat Necrosis —J Taylor Costo scapular Crepitus —A D Wright The Small Incision for Perforation of Peptic and Typhoid Ulcers —A E Porritt The Injection Treatment of Hydrocele, Varicocele, Bursitis, and Nævi —J P Ross The Anatomy of the Spinothalmic Tract in Relation to Cordotomy —J P Hosford Prognosis in Fractures of the Carpal Scaphoid —R H Boggon Removal of the Stellate Ganglion in Raynaud's Disease

THURSDAY, MARCH 5

ROYAL SOCIETY, at 4 30 —W L Garstang and C N Hinshelwood The Kinetics of the Combination of Hydrogen and Oxygen the Influence of Iodine Dr D R Hartree Optical and Equivalent Paths in a Stratified Medium treated from a Wave Standpoint.—H J Phelps The Adsorption of Substances by Fuller's Earth —*Papers to be read in title only* —*Prof L J Mordell* The Arithmetically Reduced Indefinite Quadratic Form in n Variables —J S Foster The Effect of Combined Electric and Magnetic Fields on the Helium Spectrum II —F R Terroux The Upper Limit of Energy in the Spectrum of Radium E —K R Rao and J S Badami Investigations on the Spectrum of Selenium I —J K L Macdonald Stark Effect in Molecular Hydrogen in the Range 4100 4770 A —T Alty The Reflection of Vapour Molecules at a Liquid Surface —A E Moelwyn Hughes and C N Hinshelwood The Kinetics of Reactions in Solution I II

LINNEAN SOCIETY OF LONDON, at 5 —H E Forrest and others Discussion on The Relation of the Fauna and Flora of the British Isles to those of North America.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, at 5 —Surg Capt S F Dudley Some Lessons of the Distribution of Infectious Disease in the Royal Navy (Milroy Lectures) (3).

ROYAL INSTITUTION OF GREAT BRITAIN, at 5 15—Prof J B S Haldane Respiration (3)

NORTH EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (at Literary and Philosophical Society Newcastle upon Tyne) at 6 —Rear Admiral D W Taylor Variation of Efficiency of Propulsion with Variation of Propeller Diameter and Revolutions

SOCIETY OF CHEMICAL INDUSTRY (Bristol Section) (Annual Meeting) (at Bristol University), at 7 30 —Chairman's Address

SOCIETY OF GLASS TECHNOLOGY (London Section) (at Science Museum, South Kensington), at 7 30 —Discussion on Furnace Design —T C Crawhall Some Early Types of Glass Furnaces.—F W Hodkin Design of Modern Pot Furnaces —L E Norton Design of Modern Tank Furnaces

CHEMICAL SOCIETY, at 8 —F L. Gilbert, R R Goldstein, and Prof T M Lowry: Studies of Valency Part XV Absorption Spectra of Polyhalide Ions —R V Henley and E E Turner The Reactions of Substituted Ammonium Aryloxides and of Related Compounds Part I The Preparation and Thermal Decomposition of some Tetra substituted Ammonium Aryloxides

ROYAL SOCIETY OF MEDICINE (Tropical Diseases and Parasitology Section), at 8.—Major P G Edge The Uses and Scope of Vital Records in the Tropics.

FRIDAY, MARCH 6

ROYAL SOCIETY OF MEDICINE (Otology Section), at 10 30 A M —Discussion on Effects on Hearing after Fractured Base of the Skull Lessons Resulting Therefrom

ROYAL SANITARY INSTITUTE (at Guildhall, Swansea), at 8 —H R. Tighe and others Discussion on The Rheumatic Child —Dr J M Morris E Morgan, and others Discussion on Housing

ROYAL SOCIETY OF MEDICINE (Laryngology Section), at 5

PHYSICAL SOCIETY (at Imperial College of Science), at 5 —Dr G M B Dobson A Photoelectric Spectrophotometer for Measuring the Amount of Atmospheric Ozone —G F Tagg, Practical Investigations of the Earth Resistivity Method of Geophysical Surveying —W E Pretty: Displacement of Certain Lines in the Spectrum of Ionised Oxygen (O II, O III), Neon (Ne II), and Argon (A II).

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Sir Arthur Keith Demonstration of the Nerve Supply of the Alimentary Tract and the Nature of Auerbach's Plexus

SOCIETY OF CHEMICAL INDUSTRY (Glasgow Section) (in Grosvenor Restaurant, Glasgow), at 6.30.—Annual Business Meeting

SOCIETY OF DYERS AND COLOURISTS (jointly with Society of Chemical Industry) (at Engineers Club Manchester), at 7 —S. M Neale The Action of Caustic Soda on Cellulose.

INSTITUTION OF ELECTRICAL ENGINEERS (Meter and Instrument Section), at 7 —J Urmston The Electrical High Pressure Testing of Cables and the Localisation of Faults

JUNIOR INSTITUTION OF ENGINEERS (at Science Museum), at 7 —The Historic Locomotives at the Museum

INSTITUTION OF MECHANICAL ENGINEERS (Informal Meeting), at 7 —A M Hug The Netherlands East India State Railways and Electrification (Lecture).

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Pictorial Group), at 7 —Informal Meeting

GEOLOGISTS ASSOCIATION (in Architectural Theatre, University College), at 7 30 —Dr C A Matley The Deserts of California (Lecture).

ROYAL INSTITUTION OF GREAT BRITAIN at 9 —Dr G M B Dobson Ozone in the Upper Atmosphere and its Relation to Meteorology

SATURDAY, MARCH 7

ROYAL INSTITUTION OF GREAT BRITAIN, at 3 —Lord Rutherford Recent Researches on the Alpha Rays (1).

ROYAL SOCIETY OF MEDICINE (Anæsthetics Section) (at Bristol).

PUBLIC LECTURES

SATURDAY, FEBRUARY 28

HORNIMAN MUSEUM (Forest Hill), at 3 30 —A M Hocart Spirit Worshippers of the South Seas

MONDAY MARCH 2

UNIVERSITY OF LEEDS, at 5 15 —Prof G Elliot Smith Some Factors in Mind Making

SCHOOL OF ORIENTAL STUDIES, at 5 15 —Prof B Hrozny Excavations of Kultepe The Hittites (Succeeding Lectures on Mar 3 and 4)

IMPERIAL COLLEGE—ROYAL SCHOOL OF MINES, at 5 30 —Dr W Rosenhain Hardness and Hardening (Succeeding Lectures on Mar 9, 16, and 23)

TUESDAY, MARCH 3

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL, at 5 15 —Dr C H Andrewes Immunity in Virus Diseases (1).

GRESHAM COLLEGE, at 6 —A R Hinks Astronomy in Twelve Chapters a Summary of Recent Advances (Succeeding Lectures on Mar 4, 5, and 6.) (Gresham Lectures)

WEDNESDAY, MARCH 4

KING'S COLLEGE, LONDON, at 5 30 —Dr H P Biggar The Great Age of Discovery The First Explorers of the North American Coast.

UNIVERSITY COLLEGE at 5 30 —Dr C Pellizzi Pisa (*in Italian*).

BELFAST MUSEUM AND ART GALLERY, at 8 —A P Fitzgerald Traffic Dangers and how to avoid them

FRIDAY, MARCH 6

CHEMICAL SOCIETY (at Institution of Mechanical Engineers) at 5 30.—Prof H Wieland Studies on Biological Oxidation (Pedler Lecture).

SATURDAY, MARCH 7

HORNIMAN MUSEUM (Forest Hill) at 3 30 —Miss I D Thornley Mediæval Maps and Travellers Tales

CONFERENCES.

FEBRUARY 27 AND 28.

ASSOCIATION OF TECHNICAL INSTITUTIONS (at Merchant Taylors Hall, E C 2).

Friday, Feb 27, at 11 A.M —Lord Eustace Percy Introduction of Major Gen Sir Philip Nash as President Elect

Principal B Mouat Jones *Technical Education in Russia.*

Friday, Feb 27 (*afternoon*) and *Saturday, Feb* 28 (*morning*)—

G H Gater A Descriptive Account of Technical Education in London

Comyns Carr Industrial Administration

Principal J A Todd National Certificates in Commerce.

J W Ramsbottom Commercial Education in America.

MARCH 5 AND 6.

INSTITUTION OF CHEMICAL ENGINEERS (Annual Corporate Meeting).

Thursday, Mar 5 (at Chemical Society), at 2.30—

Dr W H Gibson Flax Wax and its Extraction.

Dr R G Israel The Recovery of Gum from Fossil Kauri Timber

I W Humphrey *The Extraction of Terpene Chemicals from Waste Pine Woods*

(At Institution of Civil Engineers), at 6 30.—Baron Gian Alberto Blanc The New Italian Leucite Industry (Public Lecture).

Friday, Mar 6 (at Hotel Victoria), at 11 A M —Presentation of the Osborne Reynolds Medal, the Moulton Medal, and the Junior Moulton Medal

At 11 45 A.M —The President and others Discussion on The Education and Training of the Chemical Engineer

At 2 15.—Dr D M Newitt The Flow of Gases at High Pressures through Metal Pipes

CONVERSAZIONE AND EXHIBITION.

SATURDAY, MARCH 7

GILBERT WHITE FELLOWSHIP (at 6 Queen Square, W C 1), at 3.

SATURDAY, MARCH 7, 1931.

Scientific Method in International Affairs.

THERE is a widespread tendency to hold science, and possibly chemistry in particular, responsible for many of the worst evils of modern warfare, which is perhaps the more dangerous to society because it is apt to discredit the voice of science When a distinguished chemist like Dr H Levinstein points out that attempts at chemical disarmament or the abolition of chemical warfare, except as part of a general disarmament plan, are largely futile and may be highly dangerous because of the close relationship between chemical warfare and the ordinary operations of chemical industry, he is straightway charged in some quarters with a fatalistic war mentality

When the charge against science is examined a little more closely, its gravamen will be found to reside in part in the prejudices of those whose deep-rooted habits and instincts have been disturbed by the impact of scientific discovery Not only have the character and potentialities of warfare been transformed by scientific discoveries and their industrial development, but also scientific methods of transport and of sanitation have enormously enlarged its scale and scope The ramifications of modern warfare extend so deeply into the fabric of industrial life that all distinction between combatant and non-combatant has largely disappeared

It is essentially applied science that has made warfare a matter no longer of armies and navies but of whole populations, and this and the failure of defensive measures to keep anything like pace with the development of offensive weapons have forced on civilisation the realisation that we must learn alternative methods of settling our international disputes or face the probability of the destruction of civilisation The supreme lesson of the War is that war between the highly civilised nations has been industrialised, and by its all-embracing needs has ceased to be a directable instrument af policy

When the control and direction of war are no longer in the hands of statesmen, its renunciation as an instrument of national policy becomes inevitable Fundamentally, it is true that just as the growth of modern science changed human relationships and, finally, by mastering the forces of Nature, made slavery an anachronism, so it has now changed the relations and policies of nations and challenges society to find a substitute for war Beneath this challenge there lies man's imperative need of retaining or securing intelligent control

over social forces if he is to continue to be master of his fate, and of finding new methods now that the danger and inadequacy of the old are revealed

While, however, most thoughtful men have welcomed the renunciation of war as an instrument of national policy, only the foolish or fanatical imagined that international disputes or causes of war would forthwith disappear The problem of peace is, in truth, exceedingly complex Not all the world is civilised, nor all that claims to be, and in the uncivilised condition of the world, war has formerly been an instrument against criminal aggression as much as it has been such an instrument itself There is need for the development of a science of peace not merely the elaboration of alternative methods of settling international disputes, but also the scientific study and impartial examination of all the complex factors, economic, social, political and racial, involved in controversial problems which are sources of international friction and possible *casus belli*, if the Pact of Paris is to be transformed from a pious hope or gesture into an abiding and dominant factor in international relations It is primarily from science that society must learn scientific principles and methods of unravelling such problems and reducing them to their elements, and the responsibility for constructive thought and statesmanship is one from which scientific workers cannot escape

A striking example of the efficacy of such scientific methods when applied to international affairs is to be found in the Pacific The impartial research carried out during the last five years by the Institute of Pacific Relations on such delicate matters, involving embittered national feelings, as the South Manchurian railway, the exclusion of Japanese immigrants from California, extraterritoriality in China, have transformed the menacing problem of the Pacific into one that promises to yield to treatment that is essentially scientific Research into questions like food and population in their bearing on emigration and immigration, for example, has done much to facilitate the settlement of acute problems on the basis of facts and not of prejudice with its evitable friction So successful, indeed, has been this method that when the volumes recording the preparatory work of the Kyoto Conference of the Institute were presented at Geneva last year, the Secretary-General of the League of Nations expressed the hope that this method of dealing with dangerous issues might soon be applied to Europe

As a direct outcome of this work of the Institute of Pacific Relations, Prof J T Shotwell, its research director, worked out during the same Assembly a scheme for a European institute of research constituted on similar lines. This institute is intended to apply the spirit and technique of scientific inquiry to the economic and social problems incidental or inimical to a civilisation of peace It will be non-political, and its aims are to study the social, economic, and cultural problems common to various nations, more particularly the problems arising from invention and discovery, to extend international co-operation in this field, to co-ordinate the results of research and, in the light of the facts thus found, in concert to investigate the underlying causes of international difficulties Its functions will be solely those of research and publication of the facts as ascertained

Although the importance of this proposal was recognised by the delegates of several nations, it has yet to receive official recognition and discussion The scheme must commend itself to all scientific thinkers as a sane alternative to our present method of handling controversial questions and allowing them to be inflamed by partisan propaganda It is a method by which science can assist society through the dangerous interval between the renunciation of war, as too dangerous an instrument, and the firm establishment of other methods of dealing with international disputes

Already the technique and efficiency of conference are being steadily perfected The proposed institute offers a fair prospect of eliminating political propaganda and reaching agreed settlements as a result of scientific inquiry. It opens fields of constructive activity before the Institute of Intellectual Co operation and before such national institutions as the W H Page School of Historical Research and the Royal Institute of International Affairs in Great Britain However unjustly science has been blamed for the misuse of scientific discoveries, scientific men have not always been fully mindful of their responsibility as citizens No opportunity like the present has, however, yet confronted them of promoting the scientific study of international relations and ensuring the use of science for constructive purposes Wisely used and directed, the projected institute of research may demonstrate that the humanising effect of scientific thought on *res publica* is no less profound than its application in industry. That quest for truth which inspires every scientific investigator supplies also the driving force for this experiment: *Magna est veritas et praevalebit !*

Diamagnetism, Field Strength, and Crystal Structure.

RATHER a long time ago,[1] I directed attention to the fact that there seemed to exist a correlation between the following three properties of a metal (*a*) the crystal system to which the metal belongs, (*b*) the change in electrical resistance of the metal in a magnetic field, (*c*) the diamagnetic susceptibility, and possibly (*d*) the Hall effect

As an example I gave the following data

	χ	
Bismuth	$-1\,40 \times 10^{-6}$	hexagonal
Graphite	-5	
Antimony	$-0\,815$	
Tellurium	$-0\,303$	
Cadmium	$-0\,185$	
Zinc	$-0\,151$	
Silver	$0\,201$	regular
Gold	$-0\,152$	
Lead	$-0\,120$	
Copper	$-0\,085$	

Beginning with bismuth and ending with copper, the metals are given in the order of biggest change of resistance in the magnetic field In the same paper I came to the conclusion, when reviewing the results of D E Roberts[2] on the change of resistance of graphite in the magnetic field, that the so called free electrons could not be made responsible for the conductivity in this case, as the electrons clearly do not show any influence of a Lorentz force acting on them, which should be impossible in the case of the electrons being free It followed that the electrons have to go from one atom to another one that is, they are almost entirely bound, as in the case of graphite, or partly bound, as in the other metals One would say now that it is clear that the outer electrons of the atoms are responsible for a big part of the electric conductivity, and at the same time they are in a large way responsible for the diamagnetic susceptibility In the case of bismuth, the fact that the directions of maximum change of conductivity and of maximum susceptibility are at right angles indicates this still more strongly

As seen, those views were derived immediately from the direct results of measurements, yet they do not seem to have attracted much attention No idea, however, was offered as to the meaning of the relationship, In this respect, during the last few years, following the same mode of reasoning, Ehrenfest has made some useful suggestions in his papers on the diamagnetic susceptibility of bismuth[3] For this substance he states a working hypothesis agreeing with the views mentioned above, and giving at the same time an explanation of the very big value of the diamagnetic susceptibility of bismuth As is well known, he explains the extraordinarily high susceptibility of bismuth by the fact that in this metal the outer electrons do not move around a single atom but around several of them The surface of their orbits is then large, and hence there is high susceptibility It seems to me that this theory is a very valuable help in understanding the results of the susceptibility measurements

It was the idea of 1914 that made us undertake new measurements Mr Schubnikow and I had found that the change of resistance of highly purified bismuth is a very complicated function of field strength and orientation of the axes at low temperatures Now here we can decide whether such a relationship as mentioned does exist really for bismuth: the diamagnetic susceptibility up to now had always been found to be a very simple and regular function of the field strength and the orientation of the axis[4] If the suggested relationship exists, this should no longer be the case for crystals that show a complicated change of resistance We have had some very pure crystals grown, and Mr Van Alphen and I have measured their susceptibility as a function of the field strength at 14° K and 20° K The result was in quite good agreement with our reasoning This will be seen from the accompanying graphs, which we publish without drawing further conclusions from them Fig 1 gives the susceptibility as a function of the field In Fig 2 the magnetisation curves of bismuth are given In the same graph the curve is given indicating the change of resistance of bismuth with the field strength (already described by Schubnikow and De Haas[5]) It is clear that the curve showing change of resistance, indicated by ⊡, and the curve showing the magnetisation, indicated by △, are closely related: in fields where the resistance increases, the magnetisation remains nearly constant, where the magnetisation increases, the resistance remains constant This seems to indicate the double part played by the outer electrons: when adding

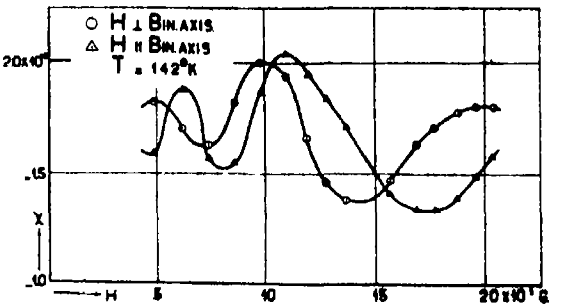

FIG 1

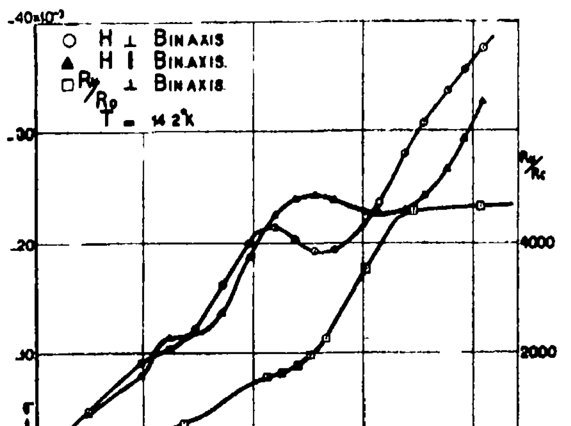

FIG 2

much to the susceptibility, they do not change the resistance, and vice versa

Though I am not able to give a suggestion of a theory which would be capable of predicting the curves, there is one remarkable fact to which I wish to direct attention, and for which I should like to suggest a possible explanation The curves not only show parts where the magnetisation remains constant in an increasing field, but also where this value even decreases It seems to me that this may be due to

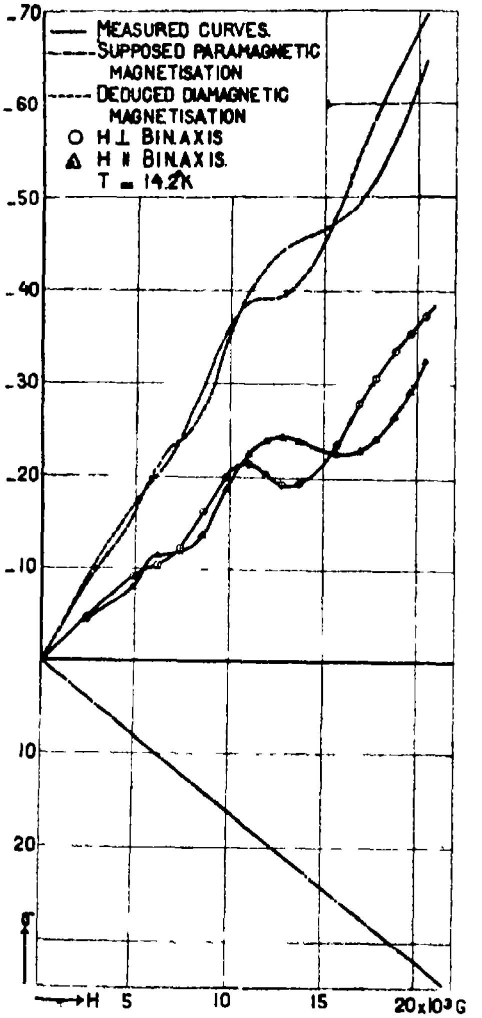

FIG 3

a superposition of the diamagnetism of the outer electron, which may show then always either an increasing or constant value, and a paramagnetism, due to the rest of the atoms, which would show a steadily increasing value Fig 3 indicates this theory the straight line gives the supposed paramagnetic magnetisation From this and from the measured curves (which are the same as in Fig 2) the upper curves, giving the supposed behaviour of the diamagnetic magnetisation, are deduced The fact that only at very low temperatures does the decrease of magnetisation take place would be due to the fact that at higher temperatures the paramagnetism (which might be supposed to follow to a first approximation the Curie law) is still too small to have this influence In support of this suggestion it may be noted that whereas the diamagnetism increases rather much from room temperature to the boiling-point of hydrogen, no further increase takes place between the boiling-point and the triple point the increase of diamagnetism would be compensated for in this region by the increase of the paramagnetism. The increase in diamagnetism may be due to the fact that the large orbits of the Ehrenfest theory are disturbed at higher temperatures the larger temperature motion of the atoms in the lattice may account for this, the large motions of the atoms caused by the melting of the metal destroys them entirely However, the mean paramagnetic moment of the rest of the atom would have to be small in order to show the right value of magnetisation in the temperature region of liquid hydrogen Anyhow, further work at the temperatures of liquid helium will bring more light in these questions

Change of Resistance in Magnetic Fields

UNTIL recently, the theory of conductivity put forward by Sommerfeld and Bloch did not succeed in explaining the change of resistance in magnetic fields If R' is the resistance in a magnetic field H, R that without magnetic field, then for weak fields the change of resistance $\Delta R = R' - R$ follows theoretically as well as experimentally the law [1]

$$\Delta R/R = B\ H^2 \qquad (1)$$

The absolute magnitude, however, of the coefficient B was found experimentally to be about 10,000 times greater than Sommerfeld's theoretical value But according to Peierls,[2] one can obtain the right order of magnitude for the magneto resistance effect by taking into account that the electrons in a metal are not moving freely, but are strongly influenced by the potential of the metal atoms Peierls gets the result

$$B = B'\ \kappa\ \left(\frac{E_0}{kT}\right)^2 \qquad (2)$$

where B' is the value of B calculated by Sommerfeld,[3] E_0 is the limit energy of the Fermi Dirac distribution of the conductivity electrons, which is about 300 times as big as kT for room temperature, and κ is a constant which measures the deviation of the motion of the conductivity electrons from field-free motion In single crystals κ depends on the direction both of the applied magnetic field and of the current relative to the crystal axes, but not on the temperature The value of κ required to explain the experiments is about 0 1, which seems reasonable, whereas the exact theoretical value cannot be calculated at present

A check of the theory can, however, be made by considering the temperature dependence of the magneto resistance effect Inserting Sommerfeld's value for B' and E_0,[4] we get

$$B = \frac{\pi^2}{12}\ \frac{1}{(en)^2}\ \kappa\ \frac{1}{R^2} \qquad (3)$$

Here all factors on the right-hand side are independent of the temperature except the specific resistance R As regards dependence on temperature, therefore, the relative change of resistance in a given magnetic field is inversely proportional to the square of the resistance, the absolute change is inversely proportional to the resistance itself The same result may be obtained by a more exact calculation, using Bloch's conductivity

theory If B_0 and R_0 refer to room temperature and B and R are measured at any other temperature, we have from (3)

$$B_0 = B\left(\frac{R}{R_0}\right)^2 \qquad (4)$$

The two last columns of the accompanying table are calculated according to (4) and show a good agreement

VARIATION OF B WITH TEMPERATURE

Faraday's First Successful Experiment on Diamagnetism

IN my discourse on "Tyndall's Experiments on Magne crystallic Action", delivered at the Royal Institution on Friday, Jan 21, 1927, and published as a supplement to NATURE of May 7 of that year, I gave a short account of Faraday's first successful experiment on diamagnetism He used a piece of heavy glass which he described in his Diary as No 174 At that time I searched through all the specimens of Faraday's heavy glass in the Royal Institution but was unable to find it It has just turned up, being contained in a box which Mrs Tyndall has most kindly allowed me to examine

The box was presented to Prof and Mrs Tyndall by Faraday, and it contains a number of specimens which the latter used in this series of diamagnetic experiments This piece of glass is actually the first object in which Faraday found diamagnetism to be shown

Mrs Tyndall has kindly promised that the box and its contents shall be on show at the Faraday Centenary Exhibition in the Albert Hall next September

Cambridge Expedition to the East African Lakes

THE expedition, which is being financed by scientific societies and the University, left England in October and is at work on the rift valley lakes of Kenya The object of the expedition is twofold First, to continue studies on the ecology of the East African lakes which were started by the Government fishing surveys of Lakes Victoria, Albert, and Kioga in 1927–28, and at the same time to make thorough collections of the faunas of Lakes Rudolf, Baringo, and Edward, which have previously received only a cursory scientific examination, secondly, by studying the old lake beaches and deposits, to continue farther north the investigations made around Lakes Nakuru, Elmenteita, and Naivasha by Mr L S B Leakey and the biologists of the East African Archæological Expedition It is hoped to link up evidence from lake beaches, the distribution of the present lake faunas, and the chemical constitution of the waters into a unified whole, and so to work out, so far as possible, the previous distribution of land and water during the pluvial periods

The personnel of the expedition consists of Dr E B Worthington (leader), Mr L C Beadle, whose special study is that of the chemical constitution of the waters and its relation to the fauna and flora, and Mr V E Fuchs, geologist, who is concentrating on the old lake beaches In addition, through the collaboration of the Kenya Government, Capt R E Dent, assistant game warden, has accompanied the expedition, giving invaluable assistance in many ways

The first two months have been devoted to a preliminary examination of Lakes Naivasha, Baringo, and Rudolf, and to fixing camp sites and transporting boats to the lakes in readiness for future work Lake Rudolf lies far to the north, extending beyond the Kenya Abyssinia border Some difficulty was experienced in transporting the equipment and a 20 foot metal life boat, lent to the expedition by the railway authorities, the 260 miles beyond the railhead to the lake This is the second boat to have reached Lake Rudolf, the first having been lost some years ago, soon after her first cruise The lake is low lying in a wide desert area, so that the climate is hot, the daily shade temperature reaching 100° F Living under canvas is uncomfortable owing to the heat, the bad water, and the high winds prevailing Consequently a hut has been constructed out of local materials to afford protection and to serve as a laboratory

All three lakes lie in closed drainage basins, and there is no previous information about their depths, except that of Naivasha This lake, at 6200 ft above sea level, has an area of 60 square miles and a maximum depth of 20 metres Baringo, at 3000 ft, has an area of some 50 square miles, and its floor proves to be silted up to an almost even depth of 7 metres Lake Rudolf, a tract of water 180 miles long by some 30 miles wide, lies at 1400 ft above the sea The deepest sounding yet made is 63 metres near the middle of the lake, this shows that Rudolf, though a true rift valley lake, is of the shallow type By comparison with the lakes of the western rift it resembles Lake Albert, depth 47 metres, rather than Lake Tanganyika, depth 1435 metres, or Lake Nyassa, 786 metres

Lakes Naivasha, Baringo, and Rudolf are alkaline owing to soda derived from the lavas of the rift valley The water of Naivasha has an alkalinity of 0 003 normal, of Baringo 0 005 N, whereas Lake Rudolf consists of a strong solution of soda with a normality of 0 023 In the latter lake the concentration of soda salts due to evaporation and the recent lowering of the lake level have caused precipitation of lime from the water This can be associated with the deposition of calcareous tufa some distance above present lake level, and also must have had its effect on the constitution of the lake fauna

Concerning the faunas, Lake Naivasha, having a single small indigenous fish, *Haplochilus antinorii*, and lying in a populated area, has for the last five years been the seat of an experiment on the introduction of other fishes for commercial and sporting purposes. This must have altered the ecology considerably, and it may have caused the extermination of some small members of the invertebrate fauna The present

fauna of Lake Baringo is poor, but shows affinities with that of Lake Rudolf to the north. Rudolf has a rich fish fauna, showing marked similarity to that of Lake Albert in Uganda and of the Lower Nile. This is proof that the lake was formerly connected to the Lower Nile system, although the present watershed between the lake basin and the Sobat tributary of the White Nile is many hundred feet above the lake level. Lake deposits over a wide tract of desert country near by and a beach at 550 ft. above present lake level show definitely that the lake was previously of much larger extent than at present. By correlation of the beach levels and by further comparison of the living and fossil faunas, it is hoped to produce important evidence concerning the pluvial periods.

The next few months will be occupied by further work on these three Kenya lakes. Later in the year the expedition will move to Lakes Edward and George, by arrangement with the Uganda Government.

E. B. WORTHINGTON.

Jan. 19.

The Antiquity of New Caledonia

I HAVE just received from my friend M. Lucien Berland a very interesting discussion of the spider fauna of New Caledonia, with special reference to its origin.[1] It is stated that M. Piroutet (1917) has published a detailed account of the stratigraphy of New Caledonia, in which it is established that the island was entirely submerged about the end of the Eocene. The spiders, which were described by Berland in 1924, if we add a few later records, number 153 species from New Caledonia and the adjacent (and faunally similar) Loyalty Islands. These include nine endemic genera, and no less than 95 endemic species. It is suggested that this fauna, or rather its ancestors, reached the island during Oligocene time. Since then, various oscillations have occurred, but the island has not been completely submerged. The close resemblance of the fauna of the Loyalty group clearly indicates connexion with New Caledonia in comparatively recent times.

If it could be certainly established that New Caledonia received its fauna and flora not earlier than the Oligocene, we should have a very interesting means of estimating the subsequent rate of diversification and evolution. But after long consideration of the subject, both when in New Caledonia and while later working on the collections secured, I do not believe that M. Piroutet's postulate can be upheld. The central part of the island is elevated, with steep slopes, and it is quite probable that the whole surface, which may have been above the sea during Eocene times, has been removed by denudation. In such case the present stratigraphy could not well be made to prove the theory of complete submergence. But setting aside the geological evidence, I think the character of the biota accords much better with the theory of a very ancient island, formerly connected or nearly connected (presumably north westward) with continental areas, undergoing great changes of level, and at times nearly but not completely submerged.

On any other basis it would be difficult to account for the very remarkable flora and no less remarkable molluscan fauna. Rocks in the interior are considered to be of Triassic and Cretaceous age, and while their existence does not refute the theory of submergence, there was apparently a land mass during at least a large part of the Mesozoic. The flora, studied by Compton, Schinz, Guillaumin, and others, is of such a character that Prof. Seward was led to remark: "In some respects the vegetation of New Caledonia carries us further back in the history of plants than almost any other part of the world". Guillaumin (1922) estimated the endemism of the flora as 76.5 per cent.; Compton's collections, made so recently as 1914, added ten new genera and 230 new species. Resemblance to the flora of Australia is shown by the presence of such woody genera as *Callistemon*, *Kermadecia*, *Hibbertia*, *Grevillea*, *Stenocarpus*, and *Casuarina*. Strangely enough, there is not a single *Eucalyptus*. The lowlands along the coast appear at first sight to be largely covered by *Eucalyptus*, but on closer inspection the tree is seen to be the *niaouli* (*Melaleuca leucodendron*). This tree must have some special facility for distribution, since it occurs not only in Australia, but also so far north as Siam, where (as I learn from Dr. Kerr) it is called *samet*. Without going into further detail, it may be said that it is wholly incredible to a botanist that this flora has acquired its peculiar features since some time in the Oligocene. It is equally incredible that since that time the now peculiar types migrated from somewhere else. Quite significant is the very small number of native grasses and the large number of endemic orchids. There is only one cycad (*Cycas neocaledonica*), which we saw growing by the coast near Bourail.

When we come to the snails, they tell a similar story. The endemism is tremendous, and the fauna has the aspect of great antiquity. The characteristic large edible snails, of the genus *Placostylus*, have very close relatives on Lord Howe Island, and the genus is also represented in New Zealand. The *Placostylus* of Fiji and the New Hebrides are of a different appearance and seem to be generically or subgenerically separable. (Ancey proposed the generic name *Diplomorpha* for a New Hebrides species.) The highly characteristic genus *Platyrhitida* occurs in New Caledonia and Lord Howe Island,[2] but the latter island has some remarkable snails apparently without relatives in New Caledonia. A curious case is that of the endemic *Papuina mageni* (*Bulimulus mageni* Gassier), which I found living on trees at Bourail. As Mr. Iredale pointed out to me, it appears to be nearly related to *P. folicola* Hedley of Queensland, found on leaves. It is, however, quite distinct as a species.

In other groups New Caledonia shows similar evidences of a very ancient fauna. There is the extraordinary and unique bird, *Rhinochetus jubatus* Verr. and Des Murs, forming a very distinct family. There are 18 endemic species of the earth worm genus *Acanthodrilus*. The leeches include a special genus. The diplopods or millipedes, always a good index of past conditions, present an astonishing array of endemic forms—including five peculiar genera, one of which cannot be readily placed in the system. The terrestrial Isopoda include 44 species, all endemic except two introduced cosmopolitan forms. There are numerous endemic land planarians.

On the other hand, if we postulate continental connexions in late Tertiary times, it is impossible to explain the total absence of numerous groups of animals and plants which are common in the regions which might conceivably have been thus connected.

Having written the above, I tried to develop a new argument on the other side of the question, and the following, based on the ants, appears to be worth offering. The ants of Baltic amber (Oligocene) are very well known, and have been rather recently (1914) revised by Wheeler. There are 43 genera, of which 19 (44.1 per cent.) are extinct. All the species are considered to be extinct, but some are almost identical with living forms. Five of the extinct genera are so peculiar that Wheeler classifies them as of uncertain affinities. Now, supposing New Caledonia to have received its fauna during the Oligocene, and nothing since, the present ant fauna of that island might be expected to be quite as peculiar as that of the amber,

and even more so, owing to the evolution on the island since the Oligocene

The ants of New Caledonia (77 species and varieties) were listed by Wheeler in 1927 I collected what ants I could, and sent them to Mr John Clark of the Melbourne Museum I have not been able to get any information from Mr Clark, but a mutual friend wrote me that he examined them and found no new species Thus it is probable that the ant fauna is fairly well known The commonest, or at least most conspicuous species, is *Polyrhachis guerini* Roger It must be said of these ants that, compared with those of the amber, they are a very ordinary lot, and show little evidence of the antiquity which we infer from the plants and molluscs Taking the ants alone, we should suppose them to have arrived (not counting those introduced by man) no earlier than the Pliocene There are only two endemic genera (and one sub genus), but 64 per cent of the species or races are endemic

Certainly, if New Caledonia had received its fauna during the Oligocene, and nothing since, we should expect to find 100 per cent of endemism as regards species, and as for genera, there is much truth in Mann's remark (1919) that "the Melanesian sub region (including Vanikoro, the New Hebrides, New Caledonia, and Fiji), like the Chilean and Malagasy, might be described as a biological conservatory, where types once tropicopolitan have been isolated and preserved, free from invasion" Yet the last sentence is too extreme, for there evidently has been invasion during late Tertiary time, but apparently of the accidental type which is characteristic of islands Neither the Australian nor the Malayan biota has come over as it must have done with complete land connexion We may infer that many of the peculiar generic types of New Caledonia had their origin on the land mass of which it is a fragment, but this cannot, in any particular case, be actually proved

The Meaning of Existence

I DO not know whether anyone has directed attention to the striking agreement of the conclusion of "The Mysterious Universe" with the final form in which Kant expressed his conclusion concerning the nature of the objective world in the "Critique of Judgment" My particular reference is to Remarks 1 and 2 appended to the 57th Section In this passage Kant makes the distinction between the *Æsthetic Idea* and the *Rational Idea*, and it marks the transition from the consideration of the æsthetic judgment of taste to that of the teleological judgment of purpose in Nature But the real significance of the passage is seen to lie in Kant's complete grasp of the relation between the intuitive knowledge of the world in sense perception and the objective knowledge of the world in scientific reasoning It is this which makes Kant's theory so relevant to the modern scientific interpretation of physical reality

I do not claim for Kant any premonition of Sir James Jeans's conception of God as the great mathematician Such a concept of God follows from a view of the nature of scientific truth impossible in Kant's generation What I have in mind is the forcible bringing home of the fact that the real world of science resembles a thought rather than a thing Kant expressed it in terms of purposiveness In the æsthetic judgment of taste, the imagination judges the beautiful in accordance with the principle of a purely subjective purposiveness, in the teleological judgment, the understanding objectifies purpose in Nature In other words, Nature is objective thought

It is this final outcome of Kant's theory which brings his philosophical problem into line with the modern scientific problem It starts with the autonomous world of sense perception, which, as Berkeley proved in a simple argument which has never been undermined, is entirely subjective Our perceptions exist nowhere but in our mind The objectivity of the world is a logical inference, and the form it assumes is a construction of thought Is it strange, then, that when we study this world scientifically we find it resembles a thought rather than a thing? What we find difficult to understand is that in discovering this we are not discovering the world to be illusion, but positively real When we say the world is thought, we mean that mind is original existence, that perceiving, thinking, reasoning are the expression of its activity, and that thought is the fixed form of its objectivity This certainly was the meaning of Kant, however halting his earlier attempts to express it It is, if I mistake not, Sir James Jeans's meaning, and certainly it is mine

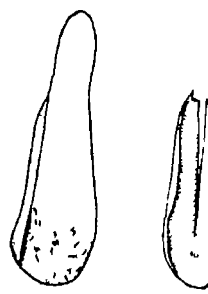
Morphology of the Pharynx of Female *Culicoides* and its Taxonomic Importance

WHILE studying the structure of the pharynx and buccal cavity of some female *Culicoides* in an attempt to correlate their affinities, if any, with the taxonomy of the group, it was found that the structure varies considerably in both the local and exotic forms In the case of *Culicoides pulicaris*, a European species, it is found that the pharyngeal armature is distinctly of *Phlebotomus* type,[1] inasmuch as it not only bears distinct serrations posteriorly, but also is furnished along one of its walls with a thin, rather deeply chitinised, pigmented ridge, which in its turn carries a series of backwardly directed teeth (Fig 1, *a*) The two local Indian species, namely, *Culicoides oxystoma*, Kieff, and *C peregrinus* Kieff, on the other hand, have pharyngeal armatures which apparently bear very little similarity with its related exotic form The pharyngeal armature of these two forms is horseshoe shaped (Fig 1, *b*), that is, the two arms are free at the proximal end, and they appear to be undivided at its distal region, leaving a very thin lumen in between, which communicates posteriorly with the alimentary canal The two free ends simulate the open ends of the shells of a bivalve mollusc, and each bears a few filamentous, outwardly directed processes The lateral fringes of the pharynx bear inwardly very fine serrations The differences between the structures of the pharyngial armature of the two Indian species are as follows In the case of *C oxystoma* the lateral edges of the armature are somewhat more overlapping in the middle, and the lateral serrations are less distinct than those of *C peregrinus*



a *b*
FIG 1 ×200

I have also traced two sets of muscles on each side of the dorso lateral walls of the pharynx which apparently aid in the creation of vacuum, thus causing an inrush of blood through the fine channel of the pharynx

Whether the structure of the pharyngeal armature will play an important rôle in the classification of female *Culicoides* depends considerably on observations on a larger scale, meanwhile, a preliminary observation of this nature, to elicit further observations on the subject, would not be out of place A detailed and more confirmatory result in this direction will be published elsewhere as specimens of both local and exotic types are forthcoming

The False Killer Dolphin

WITH regard to the occurrence of *Pseudorca crassidens* in Ceylon, to which reference was made in NATURE of Dec 6, 1930, p 892, and Jan 10, 1931, p 60, the full circumstances were not recorded at the time, owing to a printer's lapse An account of the stranding of a school of 167 false killer dolphins off the northern coast of Ceylon is now in the press and will be published in the *Ceylon Journal of Science* (Sec B) This species was previously recorded from Ceylon about forty years ago

The distribution of this species presents points of exceptional interest Apart from the few records from the north west European coast, the known distribution of *Pseudorca crassidens* is not inconsistent with the view that it is a sub antarctic oceanic form which occasionally wanders northwards in large schools into the Pacific, Atlantic, and Indian Oceans Is it not possible to regard the occurrence of this species in the North Sea as fortuitous ? I am inclined to this opinion and regard the three recorded appearances of this cold water species off the coasts of South India and Ceylon as less remarkable than the comparatively few records from the North Sea

Whales, presumably from the southern seas, are not infrequently stranded on the Ceylon coast, but precise records of such occurrences are difficult to obtain, owing to (*a*) the ignorance of the fishing population, (*b*) the inaccessibility of a large part of the coast, and (*c*) the rapidity with which a whale carcase disintegrates in the tropics

Pseudorca crassidens has been described as a common form in certain parts of the southern seas, and I agree with Sir Sidney Harmer that there is little justification for the statement that this species is on the verge of extinction

An Unusual Ice Formation

ON the morning of Saturday, Jan 31, after a frosty night, we discovered in the bird bath on the lawn a remarkable ice structure The bath is a circular metal basin, 10 in in diameter at the rim, with a concave base admitting of a maximum depth of 2 in of water in the centre There was a solid mass of ice of not less than 1 in and not more than 1¼ in maximum thickness, with a level (though not smooth) surface 8 in in diameter From the centre of this rose a pillar of ice, in the form of a triangular prism, 2¼ in high, tapering slightly downwards and flat topped The plan was a nearly right-angled (very slightly obtuse-angled) triangle, the two shorter sides measuring 1¼ in and ¾ in respectively · the hypotenuse was slightly curved and irregular, not convenient for measurement When warm water was poured into the bath, the ice melted in contact with the sides, and the whole could easily be lifted out in one mass, the pillar being used as a handle Certain appearances suggested that the pillar might be hollow, but I did not break it across, so that must remain doubtful The combined block of ice was placed in a shaded place and, though melting slowly, retained its strange appearance through the whole of the day

I am indebted to a number of my colleagues, and particularly to Prof A O Rankine and Dr H T Ellingham, for a very interesting discussion of this phenomenon The most feasible explanation appears to be that freezing began, as usual, at the margin of the surface of the water, and ice crystals grew inward until the surface was completely frozen except for a triangular area in the centre At this stage there was a rapid fall of temperature and the water below the surface began to freeze quickly The expansion accompanying solidification caused the excess of volume to be forced through the triangular aperture, the water freezing as it rose

Wisdom in Words

THE caption and the questions of "Inquirer" (NATURE, Jan 31, p 166) are salutary Is he, per chance, a reincarnation of Francis Bacon, who warned future experimentalists of the dangers of idols of the mind created by the speculative Schoolmen ?

The modern etymology of the word 'philosophy' has not been accepted by all scholars, including M Ragon, the French authority, of the last century, on the Egyptian mysteries He contended that ancient philosophers were scientific workers, and that their philosophy was a real science—not simply verbiage, that 'philos' does not represent here a noun, or mean 'affection' it is the term used for Eros, synonymous with πόθος, the universal, creative energy of Nature—the abstract 'desire' or procreative activity inherent in Nature Hence *philosophia* originally signified knowledge of the energies within objective phenomena, and *philosopher*, one who had assimilated in himself, or personified as it were, creative knowledge or the 'wisdom of creation', and could, therefore, experimentally demonstrate it The tradition may be true, then, that Pythagoras modestly refused to be called a philosopher ! W W L

William Hyde Wollaston

I AM collecting materials for a biography of William Hyde Wollaston (1766–1828), and would be most grateful for any documents or other information bearing on him which readers of NATURE could supply All documents would be carefully handled, and would be returned to the senders as soon as copied

The Audibility and Lowermost Altitude of the Aurora Polaris.

By Prof S Chapman, F R S

THE aurora polaris, after long study, remains in many respects mysterious, of late years, however, scientific opinion has been nearly unanimous in regard to its height in the atmosphere, locating it at about 100 kilometres and above Størmer has found trustworthy evidence, in a few cases, of its occurrence so low as 80 km Its upward extent is very variable, but at times it rises to a height of 800 km These very high auroræ seem to occur exclusively in the part of the atmosphere which, though viewed from stations in the night hemisphere, is itself still illuminated by the sun's rays, no very likely explanation of this remarkable fact has yet been proposed

The gradual accumulation of trustworthy photographic measures of the height of auroræ, observed simultaneously from two or more stations, since Størmer introduced his now well known methods, has steadily added strength to this conviction Yet from early times to the present day there have been occasional reports of auroræ situated at much lower heights, so as to be visible between the beholder and high land at no great distance Likewise there have been many accounts of auroræ having been *heard*, a thing scarcely to be credited if they are located at heights of 80 km or more Both kinds of observation have in general been viewed with suspicion

In 1918, Dr G C Simpson, in a letter to Nature (Sept 12, p 24), referred to the question of low auroræ, and recounted three cases that came under his notice during the 1910–12 Scott antarctic expedition he had asked his colleagues to direct his attention to any auroræ observed by them at low altitudes, in each instance he concluded, on personally viewing the aurora, that its situation below the clouds, or between the camp and neighbouring mountains, was only apparent—that chance circumstances combined to produce an optical illusion, distinguishable as such only on the closest scrutiny Indeed, on one of the three occasions a majority of his colleagues were not convinced by him that the appearance was only illusory

Such an examination, by a first-rate observer, of observations that were apparently anomalous, and contradictory of the results uniformly given by the best methods of observation, was of great value Since it dealt only with a few particular cases, it could not dispose of the possibility that in other cases the appearance of low auroræ was real and not counterfeit, yet it certainly showed that now and then appearances were very likely to deceive, and emphasised the need for caution in accepting reports even from the most trustworthy and convinced observers

The discussion has recently been carried to a further stage through the zeal of Mr J Halvor Johnson, of San Mateo, California, who for many years lived near, and beyond, the Arctic circle, and witnessed many auroræ During these years he observed, once only, in Alaska, in 1901, an unmistakably low aurora, which was visible between himself and a mountain about half a mile distant, rising to about 1200 feet above his own level Moreover, on this and but one other occasion he heard sounds accompanying the aurora At the time he had read little with reference to the aurora, and was ignorant of the prevailing opinion that the aurora is confined to the upper atmosphere In recent years his conviction, based on his own experience, that this opinion is not true in all cases, has led him to seek further evidence on the point, from other observers From few parts of the world is such information likely to be more readily available than from North America—Alaska and northern Canada Here, owing to the inclination of the earth's magnetic axis in this direction, a long stretch of the zone of maximum auroral frequency passes overland, in a region which, though inhospitable and sparsely populated, is yet inhabited by a large number (in the aggregate) of civilised men, including some, such as surveyors, and occasional professional men in small townships, of considerable intelligence and education Mr Johnson, recognising that low-level auroræ are at least rare, and apparently have not occurred at times and places where arrangements for measuring their altitude were available, in 1928 addressed a letter to each of the newspapers published in Alaska and the British Yukon Territory, seeking information in regard to auroral displays

In this letter Mr Johnson directed particular attention to the question of low altitude and sound, stating the position very fairly "much respectable testimony", on one hand, in favour of occasional sounds, and "exceedingly rare" close approaches of the aurora, and, on the other hand, the prevailing scientific disbelief, and the statements of many men who have travelled extensively in the arctic regions, that they have never heard auroral sounds He did not mention his own experience or conviction His letter was given a prominent place in the newspapers, and produced many replies, some of these he followed up by further direct correspondence He has lately published a small pamphlet "Concerning the Aurora Borealis" (29 pages, privately printed, at the Gazette Press, Berkeley, California, 1930), giving a selection of the letters (17 pages), accompanied by an introduction and brief historical account of the subject (11 pages) The writers of the letters include men from various stations in life, from "the simple pioneer and prospector, whose spirit of helpfulness outweighed his diffidence in writing, to the professional man of disciplined observational training"

This inquiry is in some respects similar to one made by Sophus Tromholt in Norway in 1885 Tromholt wrote in Nature (Sept 24, 1885, vol 32, p 499) that up to date, out of 103 replies bearing on the question of auroral *sounds*, 53 were from

writers who had personally heard such sounds, while a further 39 cited the testimony of others to the same effect, the remaining 21 declared they had never heard the sounds, or knew nothing of them It may be recalled also that in NATURE, Jan 8, 1927, vol 119, p 45, Prof Størmer reported that on Oct 15, 1926, H S Jelstrup and an assistant, at the observatory near Oslo, both heard auroral sounds during ten minutes which they were able to spend in the open watching the aurora, before continuing their observations, the sound was a very curious faint whistle, increasing and decreasing, seeming to follow exactly the vibrations of the aurora Unfortunately, Størmer had no successful photographs of the aurora during the period in question

Mr Johnson's pamphlet contains letters from twenty persons One of them does not refer to the two points here under discussion Seventeen testify to having heard sounds accompanying auroræ, and some cite one or more friends who can bear similar testimony, sixteen state that they have seen auroræ coming close to the ground, and, of these, twelve assert that they have seen the light against a background of mountains or other objects near the ground All these letters appear to be written in perfect good faith Several of the writers who have heard auroral sounds describe them as fairly frequent, others have heard them only on one or a very few occasions in many years

The sounds are variously described as "a swishing or rustle, like that of a silken skirt moving back and forth, very low, but yet plainly discernible", like those "that accompany small static discharges", like the sound made when "a couple of slices of good fat bacon are dropped into a red-hot pan", "they may attain a loudness comparable to that emitted by a high tension electric current when charging a set of horn gap lightning arresters", "quite audible swishing, crackling, rustling sounds", "a crackling so fine that it resembled a hiss", sounds "similar to escaping steam, or air escaping from a tire", "much like the swinging of an air hose with escaping air", "the noise of swishing similar to a lash of a whip being drawn through the air", sounds "likened to a flock of birds flying close to one's head", "not musical, it was a distinct tearing, ripping sound as when thin muslin is ripped or torn apart" One man at sea, in an open boat with four natives, on Oct 11, 1893, heard "the most fearful whizzling and crackling sounds, sounding at times as if thousands of firearms were fired within short distance", at the time there was "no wind and no clouds" Another writer mentions "loud reports similar to rifle cracks", "the air was still and the aurora was just above the tops of the birches", the few loud reports were followed by much crackling

Some of the accounts of low auroræ seen between the observer and terrestrial objects are very striking and circumstantial One writer states that he and his party (members of a government radio station, in the winter of 1917–18) were enveloped in "a light mist or fog-like substance in the aurora", a hand extended could be seen as if in a coloured fog, and a kaleidoscope of colours was visible between the hand and the body It was impossible to feel this visible fog or mist, and there was no dampness By stooping close to the ground it was possible to see under this light, which did not go below four feet from the ground The low-hung aurora lasted fifteen minutes, while great streaks and shafts of light came and went in the heavens The occasion was unique in the writer's experience

Another writer, during a brilliant auroral display, saw the light "play" down between himself and a steep glacial deposit bank about 125 feet away, he "stepped right into the aurora" Another saw an aurora between himself and a ten foot bank not more than one half-mile away, there was "immense light", "on the very surface", and a shaft of light shot up to an immense height Another in 1915 saw the familiar landscape "beautified by changing coloured lights which came and went rapidly, now bathing us, now withdrawing with a swish to a height of a mile or so", "it came down in streamers, or again as a fog (only much faster than fogs come, only a matter of seconds)", "we saw the tree trunks through the aurora", the colours being mostly, though not wholly, greens

These letters make it difficult to deny that auroræ occur, very rarely, quite near the earth, and are sometimes accompanied by noises Almost all the reports come from a belt of country about three hundred miles wide, lying roughly along the auroral zone, the belt includes the Klondike region, where is situated the township of Dawson, with a population of several thousand, several reports come from this neighbourhood The only other places along the auroral zone, likely to afford such favourable fields of inquiry, appear to be near Churchill, on Hudson Bay, the extreme south of Greenland, Iceland and the most northerly part of Norway

Since very low auroræ seem to be very rare and to be confined to localities near the auroral zone, it is perhaps not surprising that Størmer, Vegard, and Krogness should have observed no such case, or that the Polar Year (1882–83) failed to provide evidence establishing their existence, with the better organisation of auroral observation which it is hoped to achieve during the proposed new Polar Year (1932–33), there is more chance that opportunities of critical examination of these appearances will occur

These low auroræ must obviously be very different in character from those observed in the upper atmosphere, though connected with them Inability to understand their physical nature is not a sufficient ground, in the present state of knowledge, for rejecting the possibility of such occurrences, such an attitude would, for example, forbid acceptance of the reality of globular lightning The observations cited by Mr Johnson constitute at least a case for active further inquiry, and render it highly desirable that auroral investigation near the auroral zone should include not only visual and photographic observations, but also atmospheric electric registration at a well-equipped observatory

Science Medals of Great Britain, Ireland, and the Dominions

AS a supplement to the issue of NATURE of Nov 15, 1930, we published an article on medals awarded for scientific achievement, and brief classified statements relating to the various medals in the gift of institutions of the British Empire The difficulty of making the list exhaustive was obvious, and we print below particulars of further awards to which our attention has been directed

I GENERAL

Royal Society of Western Australia, Perth

Society's Gold Medal—Arising from the commemoration of the centenary of birth of Lord Kelvin, in 1924, the Society decided to institute a gold medal for award from time to time for distinguished work in science connected with Western Australia The entire initial cost was borne by voluntary subscriptions The award is made on a recommendation by a medal committee of five members, and normally at four-yearly intervals The first allotment was in 1925, to Dr W J Hancock, for pioneer research in radiology, that for 1929 was given Dr E S Simpson, government mineralogist and analyst The obverse of the medal bears the bust of Lord Kelvin

Royal Numismatic Society of London

Society's Medal—Founded in 1883, and awarded annually or otherwise in silver or bronze for distinguished services to numismatic science, the recipient may be of either sex, and there is no restriction as to nationality The first allotment was made to Charles Roach Smith, the eminent antiquary, that for 1930 to Mr P H Webb, president of the Society

British Numismatic Society

Saltus Gold Medal—Founded in 1910 by Mr John Sanford Saltus, of New York, a vice-president Awarded triennially to " the member of the Society whose paper or papers appearing in the Society's publications shall receive the highest number of votes from the members, as being in their opinion the best in the interests of numismatic science " Allotment was made in 1929 to Mr J S Shirley-Fox

University of Melbourne.

David Syme Research Medal and Prize—(Mr E O Hercus, 16 Melbourne Place, Cambridge, directed our attention to the omission of this prize Strictly, the original series comprised the awards of medals made by scientific academies and societies, but the following account will be of interest.)

Founded by the gift of £3000 by David Syme for the purpose of encouraging in Australia the carrying out of research work in biology, chemistry, geology, and natural philosophy The award takes the form of the annual bestowal of a gold medal and gift of £125 for a thesis based upon original work in the departments of science mentioned above, but preferably in connexion with the material and industrial development of Australia The thesis must either have been published not more than two years before an allotment, or published afterwards in such a manner as shall satisfy the council The prize is open to any person who has been resident in Australia for not less than five years out of the seven years immediately preceding that in which the prize is offered No professor in an Australian university and no head of a scientific department under any Australian authority is eligible

II PHYSICAL AND MATHEMATICAL SCIENCES

Institute of Actuaries

Institute Gold Medal—In 1920 it was decided to establish a gold medal in recognition of any paper or treatise of outstanding originality in actuarial science, the award not to be restricted as to nationality or sex

N B—No award of this medal has been made so far, but it should be mentioned that in 1927 and in 1929 special gold medals were struck, and bestowed respectively upon two distinguished exponents of actuarial science

British Astronomical Association

Walter Goodacre Gold Medal—Founded in 1929 through a fund provided by Mr Walter Goodacre, a past president, and for award to members in recognition of contributions to the progress of astronomy, special regard being paid to work communicated to the Association An award is made at intervals of not less than two years nor more than four years The first allotment was made in 1930 to the Rev T E R Phillips

Institution of Civil Engineers of Ireland

Mullins Medal—The Institution awards medals (or premiums) annually under the terms of a bequest by Mr M B Mullins, president in 1859–61. The medals may be of gold or silver, and refer in bestowal to meritorious papers read before the Institution The obverse of the medal bears the head of Mullins

Institute of Fuel

Melchett Medal—Inaugurated in 1930 by Lord Melchett, founder-president (1927) of the Institute, to mark the completion of his period of office, for annual award It is struck in bronze, and awarded to such person, whether a member of the Institute of Fuel or otherwise, as in the opinion of the council has done either original research or professional, administrative, or constructive work of an outstanding character involving the scientific preparation or use of fuel, provided the results of such work have been made available within recent date for the benefit of the community The allotment is without restriction as to the nationality of the recipient The first award was made to Dr Kurt Rummell, principal of the Warmestelle, Düsseldorf It is the intention of the council to invite the recipient each year to give a Melchett lecture, following the presentation of the medal

Society of Glass Technology, Sheffield

Frank Wood Medal.—In 1919, the Society, in order to commemorate the services of Mr. Frank Wood, who was the first president, to the glass industry and glass technology, inaugurated a fund and decided to found a medal in bronze; the award to be placed in the gift of the University of Sheffield, and allotted annually to students in the Glass Technology Department. The University holds the fund as trustee. The design of the medal was entrusted to Mr. P. Metcalfe, Royal College of Art, South Kensington.

British Horological Institute

Institute's Gold Medal.—The Institute was established in 1858. In 1928 a gold medal was founded for annual award, at the discretion of the council, for the greatest advance in the science of horology, or some achievement of outstanding merit beneficial to the science or practice of time measurement. The first recipient was the Astronomer Royal, Sir Frank Dyson. The reverse of the medal carries the inscription: "For having improved horology by practice and enriched it with learning."

British Institute of Radiology

Silvanus Thompson Medal.—Founded in 1918, in association with a memorial lecture, and in commemoration of Prof. Silvanus P. Thompson, F.R.S., the first president of the Röntgen Society. Distinguished workers in radiology or allied subjects, of any nationality, may be invited to deliver the lecture, and, so far as possible, choice falls alternately on a medical and a non-medical man. The medal is struck in bronze and bears the bust of Thompson. An honorarium is attached to the lectureship.

Mackenzie Davidson Medal.—Founded in 1920, in association with a memorial lecture, and in commemoration of Sir James Mackenzie Davidson, a pioneer in British radiology. Distinguished workers in radiology or allied subjects, of any nationality, may be invited to deliver the lecture, and, so far as possible, choice falls alternately on a medical and a non-medical man. The medal is struck in bronze, and bears the bust of Mackenzie Davidson. The regulations provide that the choice of lecturer shall be made each year by a joint selection committee appointed by the Institute and the Electro-Therapeutic Section of the Royal Society of Medicine. An honorarium is attached to the lectureship.

Society of Radiographers, London

Reid Medal.—Instituted as a memorial of the services of Sir Archibald Reid. Struck in silver, it is awarded annually in competition amongst members of the Society for radiographic films of merit, applicable to selected subjects which are chosen by the council. The obverse of the medal bears the bust of Reid.

Australian Chemical Institute, Sydney

Smith Memorial Medal.—Founded in 1929 to perpetuate the memory of Henry George Smith, one of the foundation officers of the Institute and a pioneer in research into the chemistry of the Australian eucalypts. The leading Australian scientific societies were represented on the memorial committee, and contributions to the fund were received from each State in the Commonwealth. It is struck in bronze, and awarded annually to that person who has, in the opinion of council, contributed meritorious service to the development of chemical science. The first allotment (1929) was made to Dr. A. C. D. Rivett, of Melbourne, for research work published during the ten preceding years.

Rennie Memorial Medal.—In the course of 1930, members of the Institute established a fund to found a bronze medal in memory of Dr. Rennie, Angas professor of chemistry in the University of Adelaide for more than forty years. He was actively associated with the formation of the Institute, and at one period was its president. It is proposed to award the medal annually, among the younger members of the Institute, for research work.

III. Biological Sciences (including Geology and Geography)

Royal Society of Tropical Medicine and Hygiene

Chalmers Memorial Gold Medal.—Founded in 1921 by Mrs. Chalmers, widow of Dr. Albert John Chalmers, author of numerous works on tropical medicine and hygiene, and student of the hygiene of the tropics. The award is made biennially, and bestowal is in recognition of research of outstanding merit contributing to the sciences of tropical medicine or tropical hygiene. There are no restrictions as regards nationality, sex, or profession. The medal bears on the obverse the head of Dr. Chalmers; on the reverse a representation of *Anopheles costalis*, and below, a spray of the cinchona plant. The first award was made in 1923 to M. Roubaud, Pasteur Institute, Paris.

Manson Medal.—A fund had been subscribed in 1921 by friends and admirers of Sir Patrick Manson, in all parts of the world, with the view of obtaining a memorial portrait. A balance in the fund being available, a bronze medal was founded in memory of Manson's fruitful work and influence in the field of tropical medicine and hygiene. The capital sum, with the allotment of the medal, was vested in the council of the Royal Society of Tropical Medicine and Hygiene. An award is made triennially to the living author of such original work in any branch of tropical medicine or tropical hygiene as may appear to be deserving of the honour. There is no restriction as to the age, sex, profession, or nationality of the author. The obverse of the medal bears the bust of Manson. The first recipient was Sir David Bruce; the last (1929), Sir Ronald Ross.

Royal Army Medical and Allied Services

North Persian Forces Memorial Medal.—In 1921 a fund was raised by certain officers of the Royal Army Medical Corps and Indian Medical Service who took part in the withdrawal of the North

Persian Forces and their subsequent dissolution Struck in silver, a medal is awarded annually for the best paper on tropical medicine or hygiene published in any journal during the preceding twelve months by a medical officer, of less than twelve years' service, of the Royal Navy, Royal Army Medical Corps, Royal Air Force, Indian Medical Service, or of the Colonial Medical Service A Memorial Committee determines the attainment of a standard of merit The first award was made in 1923 The recipient for 1929 was Capt H W Mulligan, Indian Medical Service

Obituary.

DR ALFRED P MAUDSLAY

ALFRED PERCIVAL MAUDSLAY passed away peacefully in his sleep on Jan 22, in his eighty-first year, at Morney Cross, near Hereford Born on Mar 18, 1850, at Lower Norwood Lodge, he attended first a boarding school at Tunbridge Wells and then went to Harrow He was keen in all forms of sport, particularly fishing, and shot for his school in the winning team for the Ashburton Shield Leaving school, he proceeded to Trinity Hall, Cambridge, of which he was made an honorary fellow in 1923 A visit to the West Indies was made in 1872, and from Panama and Guatemala he went north to San Francisco, on his way to New York, and there met his future wife, a daughter of Governor Morris of Old Morrisania, New York The following year, accompanied by his brother, he visited Iceland, making the ardous trip round the island, but he also tells of many pleasant days fly fishing

After taking his degree in 1875, Maudslay went to Trinidad, where he accepted his first appointment as private secretary to H E the Governor He next acted in a similar capacity to the Governor of Queensland Joining the staff of Sir Arthur Gordon as private secretary, he went to Fiji, becoming in turn Acting Colonial Secretary to Fiji, Deputy Commissioner to Tonga and Samoa, and Acting Consul-General for the Western Pacific In 1876 he accompanied Lady Gordon to New Zealand, where he spent some months, crossing into the then prohibited Maori Territory Returning to Fiji, he went to live on Tonga as Deputy Commissioner He left these Pacific islands in 1879, but it was only last year that he published a delightful autobiography of that period in "Life in the Pacific Fifty Years Ago"

Maudslay in his visit to Guatemala was so struck with the Maya ruins he had seen there that he decided to give up his diplomatic career and devote his life to exploration in Central America To that country and Mexico he made at least seven expeditions, visiting, clearing, measuring, photographing, and plotting all the then known Mayan ruins, and the results of these expeditions appeared in 1889 in the "Biologia Centrali-Americana Archæology" By this monumental work he laid the foundation of Maya research, which has since been enthusiastically taken up by German and American scholars This, unfortunately, cannot be said of Great Britain, his priceless collection of 'squeezes' and moulds (which had cost him £10,000) he presented to the nation, but they lay neglected, falling to pieces and eaten by rats, for upwards of thirty-five years in the vaults of the South Kensington Museum, until they were rescued in 1923 by Capt Joyce on behalf of the British Museum There they were pieced together and restored, and casts made and set up in a room to themselves, as they deserve, and now form the finest collection of Maya casts in the world There is an interesting and well illustrated account of these casts compiled by Dr Maudslay and Capt Joyce Maya expeditions to British Honduras, under the direction of the British Museum, have gone out annually since 1926, but the lack of public interest has made expenditure a first consideration, and were it not for the generous help of a few private individuals who supplement the small British Museum grant, it is doubtful if many more expeditions can go out without the help of the United States

When Maudslay made his seventh expedition to Central America, he was accompanied by his wife, and the result was the joint publication of "A Glimpse at Guatemala" in 1899 This charming and beautiful book is printed on hand made paper and profusely illustrated with photogravures, coloured plates, and chromo-lithographs The next work from his pen was a translation, with introduction and notes, of Bernal Diaz' "The True History of the Conquest of New Spain" for the Hakluyt Society, and it ranks among the finest of that Society's publications

In the summer of 1912, the eighteenth International Congress of Americanists met in London under the auspices of the Royal Anthropological Institute, when Maudslay was president, and when the Congress visited Oxford the honorary degree of D Sc was conferred on him for his contributions to Mexican and Mayan archæology Cambridge also honoured him by conferring on him the honorary degree of Sc D

In 1915 Maudslay was one of the joint secretaries of the Royal Geographical Society, in which he took a keen interest, specially at the time when the Society moved from its cramped quarters in Savile Row to Lowther Lodge In 1928 Maudslay published a popular edition of "The Discovery and Conquest of Mexico", with introduction and notes

It was in 1905, in Mexico City, that the present writer had the pleasure of first meeting Dr Maudslay, at a luncheon at the British Legation, sitting next to him, the conversation naturally turned on archæology, and, mentioning having visited the ruined cities of Ceylon, he said it was just 'a toss up' whether he had gone to Ceylon or Central America to excavate Immediately after luncheon

we went to the National Museum, he was very proud of his post as honorary professor of archæology there, and pointed out Maya sculptures which were wrongly labelled as Zapotec A few years later, after visiting the ruins of Palenque with the Mexican Government expedition, and remarking that it took us three days to reach them from Frontera at the mouth of the Usamacinta River, he smiled and said it had taken him nearly three months!

Throughout all his Central American travels, Maudslay seems to have been endowed with extraordinary patience and perseverance, and this, together with his charm of manner and personality, enabled him to overcome all obstacles, whether of local politics, native prejudice, lack of guides, transport or labour Maudslay always gained his point and got his way To the young archæologist he was always ready with help, advice, or encouragement, especially in the study of Maya glyphs, and it is difficult to speak in measured terms of his loss to the Mexican and Mayan student of archæology Those whose privilege it was to be numbered amongst his personal friends will perhaps best remember him for his kind and gracious disposition, his keen and sparkling eye, and his blameless life He was the type of the true English gentleman and traveller We shall not look upon his like again J C C

Mr David T Jones, C B E, chairman of the Fishery Board for Scotland, who died in Edinburgh on Feb 4, in his sixty fifth year, began his official career as a junior clerk in the Fishery Board in 1887 He was promoted after five years' service to be chief clerk, and in 1909 to be secretary to the Board During the War, he served as Paymaster Lieut-Commander, R N R, prepared a census of fishermen, and organised a fleet of fishing vessels for various patrolling and defensive purposes His special knowledge of fishermen and fishing interests, extended by this war service, was of great value in his subsequent administrative work In 1920 he was appointed chairman of the Board He was especially interested in the fisheries problems of the North Sea, and was one of the British representatives on the International Council for the Investigation of the Sea His strong support of the Scottish Fishery Board's scientific investigations is evidenced by the expansion of the laboratory facilities for this work under Dr Alexander Bowman in Aberdeen Mr Jones was of cheerful temperament, and was a very genial friend who will be missed in many circles, especially in Edinburgh

---

Mr Thomas Hebden, of Keighley, who died on Jan 3, at the age of eighty-one years, was one of the Yorkshire naturalists who, in the intervals of a business life, devoted himself to a particular branch of botany He was a correspondent with many of the leading lichenologists of his day, and this correspondence was maintained almost up to the day of his death and is reflected by the numerous references to Hebden in lichenological literature His correspondence with Nylander added several species of *Verrucaria* to the British flora, these being published under the joint names of Shackleton and Hebden in the *Naturalist* of 1892 His herbarium and scientific books have been bequeathed to the museum of his own town

---

We regret to announce the following deaths

Dr Alfred Holt, one of the joint honorary secretaries of the British Association at its meeting in Liverpool in 1923 and founder of the firm of Holt, Thompson and Co, Ltd, manufacturers of fine chemicals, on Feb 15

Prof F J Pritchard, plant physiologist of the U S Bureau of Plant Industry, who specialised in breeding disease resisting varieties of tomatoes, on Jan 13, aged fifty six years

News and Views

The president of the Russian Academy of Sciences, Dr A P Karpinsky, the distinguished geologist, is leaving his post at the Academy This decision is the outcome of his unsuccessful protests against the recent forced decision of the Academy to deprive of its membership four academicians, including such historians as S F Platonov and E V Tarle, whose scientific views have been pronounced by the authorities to be incompatible with their presence in the Academy of a communistic State It is noteworthy that at the same meeting of the Academy several foreign scientific workers were elected as foreign members It appears clear, in the circumstances, that the acceptance of membership of the Academy of U S S R must involve silent agreement with the basic principle underlying the attitude of the Soviet authorities towards science According to this principle, science is regarded as merely a means to the successful accomplishment of the Five Years' Plan, and scientific workers themselves are forbidden to express, or even to hold, independent scientific views

New Zealand has its Scenery Preservation Act, now almost twenty three years old, and still we wait to see what a British Government Commission will say about the desirability of doing something for British scenery In New Zealand the Act has worked well, as is shown by the Annual Report for 1930, a blue-book of 30 pages, with many photographs and a map in colour, issued by the Department of Lands and Survey During the year, proclamations were made setting land apart for scenic or historic reserves to the extent of 6982 acres, and these areas now bring the number of scenic reserves in the Dominion up to 851, with a total area of 511,792 acres The value of the reserves to the artist and traveller, as well as to the naturalist, is indicated in an appendix by Dr L Cockayne and Dr E Teichelmann, describing the Glacial Scenic Reserves of Westland Apart from the annual interest on the capital expended in purchasing the reserves, the accounts show that they are run for about £1276 a year, and this is offset by rents, etc,

amounting to £757 The annual interest on the invested capital is a more serious drain, amounting to £8979, for with the year's purchases the capital itself stands at just over £200,000

Anything that will lead to uniformity in the mode of reference to periodicals is to be welcomed, and even more important than uniformity is intelligibility An "International Code of Abbreviations for Titles of Periodicals", just issued by the International Institute of Intellectual Co operation ("Physician, heal thyself!"), has both merits Most wisely it is based on the rules and principles adopted by the compilers of "World List of Scientific Periodicals (1900–1921)", and differs little from them Those rules were not easily accessible, even though the British Association Committee on Zoological Bibliography reprinted them (Leeds, 1927) and circulated them to zoological periodicals The present statement, in French and English, is more clearly drawn up, and is obtainable from the Institute for 2 50 fr Intelligibility must be judged, not by the reader thoroughly familiar with the periodical in question, but by the worker in another branch Excessive contraction is therefore to be avoided it should be possible for the educated non specialist to reconstruct the abbreviated word Judged thus, some of the contractions proposed seem to "curtail the already curtailed cur" We jib at "Tms" for the *Times*, "Chi" might mean Chile as well as Chicago and who will guess "L B"? Diacritical marks should be avoided for the sake of the printers, and so we approve of "Kbh" instead of the perhaps more intelligible "Kjøb", but we object to "Ž" for "Žurnal" We could say more, but we prefer to commend this attempt to editors and authors

Cerebro spinal or 'spotted' fever has been somewhat prevalent this year, and the outbreak is the subject of a circular recently issued by the Ministry of Health This disease occurs, to some extent, every year, but in certain years the incidence may be considerably above the average After the War, when it was prevalent, the number of cases declined to 301 in 1923, since when there has been an upward trend, with 666 cases in 1930 in England and Wales This year 230 cases among civilians have been notified, about half of which have proved fatal The cases have been scattered and distributed in 36 counties, with some concentration in the West Riding of Yorkshire The disease is especially liable to attack children and young persons, and during periods of prevalence the responsible micro-organism (the meningococcus) is to be found in the nose and throat of a number of persons who are and remain well Such healthy carriers are probably of more importance than the cases themselves in spreading the disease One factor known to favour local outbreaks is overcrowding in barracks, institutions, and schools Plenty of space should be provided in dormitories, with thorough ventilation

Universities in their relationship to national and international movements are discussed in *Bulletin* No 7, 1930, pp 43, of the Paris office of the Carnegie Foundation for International Peace It contains two papers by Prof d'Irsay, of Johns Hopkins University, and Prof Bloch, of the Sorbonne, entitled respectively "Histoire Internationale des Universités", and "La Cité Universitaire de Paris" Prof d'Irsay concludes his historical survey with a generalisation contrasting the spirit in which their teaching work is conducted by universities with that of their scientific research the former inevitably nationalistic and tending to become monotonous and reactionary, the latter, which is slowly but surely becoming their dominant note, genuinely international and all the more important in virtue of the fact that scientific research is the only real force uniting the world Prof Bloch's paper gives an account of the aims, organisation, and present position of the Cité Universitaire, inaugurated in 1924, when buildings providing for the accommodation of 300 French students were begun Since then hostels have been erected on the Cité estate for Canadian, Belgian, Argentine, Japanese, American, and Indo-Chinese students, and others are in course of construction for British, Swedish, Dutch, Spanish, Armenian, Danish, Greek, Cuban, Monacan, and French provincial students By 1933 the total number of rooms will be 2500 In order to promote friendly intercourse between the students of different nationalities, a "Maison Commune", for which Mr J D Rockefeller has constituted a foundation of 90 million francs, will provide communal refectories, lounges, music room, library, gymnasia, etc, and a medical service

On Feb 25, Mr W G W Mitchell gave a lecture on "Developments in Television" before the Royal Society of Arts He pointed out that early experimenters in the field of television were handicapped through not having suitable photoelectric cells for converting changes of light and shade into corresponding electrical impulses, and also through the modern valve amplifier then being unknown But the past five years have shown that a primitive form of television is physically possible The fundamental difficulties were considered in detail As examples of the trend of development Mr Mitchell dealt with the recent demonstration of two way television in America, the various attempts made to produce a large screen picture suitable for viewing by large audiences, and the attempts that had been made to overcome purely mechanical methods by using electrical ones The American Telephone and Telegraph Co, which was responsible for the two way television system, was primarily seeking information as to the value of the addition of sight to sound in personal conversations over the telephone The extra apparatus for providing vision is bulky and the operating costs are heavy, but work is in progress to reduce these defects Speaking of large screens, Mr Mitchell referred to a recent demonstration by J L Baird of an arc lamp the intensity of which was modulated directly by a vision signal Very good brilliancy was obtained on a screen 7 ft by 3 ft at 10 ft distance by optical projection Purely electrical methods of television, such as the cathode ray method, will be more widely used as soon as the high voltages required for operating can be reduced Mr Mitchell thinks, however, that

the next development will be in the direction of zone methods used in conjunction with wired transmitting circuits Using these methods, it should be possible within a year or two to have a picture of the size and brilliancy of the cinema screen picture of to day

THE presidential address of Dr W H Eccles to the Institute of Physics, delivered last May (see NATURE, June 14, p 894), has recently been published He took as his subject the influence of physical research on the development of wireless communication From the historical point of view the address is of great value, as no one has studied more closely the development of this industry, and in addition no one else has been in personal contact with so many of the pioneers He points out that in the near future the knowledge, which has been laboriously accumulated, of the effect of atmospheric conditions on radio communication, will be utilised and that further rapid developments will take place Radio has advanced practically by leaps and bounds Some of these leaps—for example, the maturing of the triode valve—have led to the scrapping of equipment before it has earned the cost of its engineering development Industrialists naturally fear these revolutionary improvements, due often to physical research At present there is much discussion in engineering circles on rationalisation, the main object of which is to reduce the costs of production and eliminate waste in basic industries Standardisation is a useful help in this direction, and so also is the modernisation of plant and products by the introduction of the latest methods and inventions The standardisation that asks all manufacturers of certain articles to work to agreed specifications concerns engineers only, but that which calls a halt to the introduction of innovations affects physicists also This latter form of standardisation is in conflict with the principle of modernisation Physicists are often looked on askance by engineers, as their revolutionary ideas necessitate changes in manufacture As, however, they live in the laboratories whence spring the discoveries which may overturn the established order, they are admirably qualified to forecast probable developments, which will enable engineers to decide when to standardise and when to modernise

THE January number of the *Brown Boveri Review* gives an interesting record of the progress that is being made abroad in the design of electrical machinery It shows clearly that in electrical traction the advances being made are in the direction of single phase and direct current working The Simplon Tunnel, for example, has been operated for nearly twenty-four years by means of three phase current Since 1920 it has been operated by seven locomotives, which handled without difficulty the greatly increased passenger and goods traffic after the War At the beginning of last year, three phase operation was replaced by single-phase operation, the double type of current collector employed eliminating many difficulties Devices are now employed which enable the locomotives to run at four economical speeds The Italian State Railways are electrifying a number of their sections with high pressure direct current at 3000 volts The electric power is conveyed to the substations at 60,000 volts three-phase, and is then converted into direct current power at 3000 volts by 2000 kilowatt mercury arc rectifiers The design of these rectifiers is being continually improved and their size is rapidly increasing The latest design is a high power rectifier with eighteen anodes capable of supplying a direct current of 12,500 amperes Successful investigations as to the possibility of reversing the action of these rectifiers have been made It is now possible to supply electrical energy from a direct current network to a three phase network The frequency of the supply is the same as that of the three-phase generators, or it can be adjusted to any desired value from the direct current side It can be used for transferring energy from an alternating current system working at one frequency, to another working at a different frequency

THERE seems to be a need for standardising the airway beacons that are used for guiding aeroplanes at night In a paper in the *Illuminating Engineer* for February, H N Green states the requirements that a good beacon has to fulfil, and draws instructive curves to illustrate the light distribution from beacons of various candle powers A beacon has to indicate, either by flashing, or by its colour, or by subsidiary lights, its locality on the route on which it lies When flying at night over inhabited country at a height of 3000 feet, with average visibility a large number of lights can be seen These lights can be divided into two groups Local lights such as street lamps and shop windows form the first group They cease to be visible at a range of from five to six miles The second class contains the high powered head lights on motor transport These sometimes give beams of 50,000 candle power, which are visible at distances up to twenty miles The presence of these flashes occasionally makes it difficult to identify a white flashing beacon when it is more than five and less than twenty miles away The true horizon is about seventy miles distant, and if the beacon lies between twenty and seventy miles away it appears as an isolated flashing light and is easily identified It is suggested that the lower limit for the intensity of a beacon should be 100,000 'beam' candles The author discusses how the visibility varies with the height of the aeroplane and with the state of the atmosphere He makes a calculation to show the worst visibility at which flying is possible Pilots often complain that present day beacons are conspicuous in clear weather, when they are not much wanted, and disappear in bad weather, when they would be of the greatest help

AMONG recent donations received by the Zoological Department of the British Museum (Natural History) is a large album containing photographs taken in the Birunga mountain district to the north east of Lake Kivu, East Central Africa, and dealing with the home of the eastern gorilla (*Gorilla gorilla beringeri*) These photographs were taken and were presented by Mr Marius Maxwell, author of "Stalking Big Game with

A Trilogy of Science

The Torch-Bearers By Alfred Noyes Vol 3 *The Last Voyage* Pp ii + 229 (Edinburgh and London William Blackwood and Sons, Ltd, 1930) 7*s* 6*d* net

THOSE who remember the interest with which we greeted the first volume of Mr Noyes' "Torch Bearers" seven years ago will understand the satisfaction with which the concluding portion is now received This is all the greater because the third volume is certainly the best from the artistic point of view It contains one well conceived and highly interesting incident, around which the author's pictures of the past and incidental lyrics are effectively grouped, and it leads up to a full and eloquent exposition of the religious synthesis with which the history of science inspires him

It will be recalled that the governing idea of the trilogy was to present the history of science as a connected whole, but, in view of the immensity of the subject and the need of some dramatic interest for poetic purposes, to select certain crucial moments and treat them with some fullness In this way the first volume was made to turn largely round Galileo and Herschel and the second round the Darwinian controversy The third has the advantage of a real incident in contemporary life as its central thread A child on an ocean liner has to be operated on during the voyage There is no first rate surgeon on board, but communication is set up by wireless with another steamer, also in mid-ocean, on which one of the greatest experts happens to be sailing The ship's doctor carries out the operation, under the directions of the other man, but the poet, as he reflects on what is going on, hears other voices, transmitted not only through space but also through time The thought which is co-operating in the attempt to save the life of the child is really that of all the workers and thinkers in the world who have contributed to the skill and knowledge now put forth Harvey speaks and Pasteur Even the Chinese, whose culture of the silk worm had a part in Pasteur's discoveries, find a place

This is the true lesson of the poem, as it is of the growth of science itself

> All this inter dependent, intricate web,
> The invisible system of ethereal nerves,
> Connecting mind and hand with waves of will,
> Without which both were helpless, *whose are they?*

And the answer includes not only Gilbert, Galvani, Ampère, and all workers in physical science, "thousands of men, like cells in one organic brain", but also the still greater host who have worked at the sciences of life

It is a dramatic idea of the highest imaginative value, thus to represent all this collective wisdom and will coming invisibly through the darkness to the cabin of a mighty modern ship to save the life of one small child and it becomes a tragedy, when the child dies Herein Mr Noyes is faithful to the best canons of art The human spirit, like the hero of ancient Greek tragedy, in such a case rises to the height of its powers, struggles to achieve its end, and is foiled by fate Our admiration is by no means lessened, but touched, as Aristotle would have it, by awe and pity

Mr Noyes, however, goes further than the Greek tragedian or philosopher, in attempting to reconcile the failure of the particular action with the reasonableness and rightness of the whole The poet, musing again after the child's death, discovers, after death had struck down the mortal body and the dear thing had vanished from the world which but half an hour ago had "outvalued all earth's kingdoms", that something else is needed to restore his sanity and his acceptance of the universe This is the assurance which then comes to him from the infinite that there is a law and a love which will harmonise all catastrophes, and an eternal memory of which our human fragments are but parts The

latter portion of the poem thus becomes a religious rhapsody, rather on Wordsworthian lines

This concluding volume of the trilogy confirms our impression of seven years ago that Mr Noyes has conferred a signal service both on English poetry and on science The thing is beautiful and interesting in itself, and is bound, especially when it appears in one volume, to attract a large number of serious readers who would otherwise never connect the thought of science with that of poetry It does this also in a novel way, not dreamt of by earlier poets, such as Wordsworth and Shelley, who hoped for an infusion of science in the language and images of poetry Mr Noyes turns rather to the idea of filiation which has become dominant in the last hundred years, and follows it out in certain episodes in the history of science, which is the field where it is best displayed

Mr Noyes' dramatic method of seizing striking incidents in the lives of men of science is the best calculated to rouse popular interest, though it has the disadvantage, from the philosophical point of view, of throwing into unfair relief certain persons, such as Francis Bacon and Renan in the present volume, whom the author chooses as foils for his heroes But how, one may ask in palliation, does Julius Cæsar fare at the hands of Shakespeare, or Cromwell or Louis XI at the hands of Scott ? Let us be thankful for an art which makes vivid for us the clash of personalities in the past and, in Mr Noyes' case, of personalities in a sphere hitherto scarcely touched by poets, and, as history, treated as a thing apart In an age of specialism, when a synthetic spirit is the thing most needed, alike in politics and in thought, what could be more useful than to bring, as Mr Noyes has done, poetry and history and science together in a careful, interesting, and at times very beautiful piece of work ?

Vitalism and Mechanism

The Nature of Living Matter By Prof Lancelot Hogben Pp ix + 316 (London Kegan Paul and Co, Ltd, 1930) 15*s* net

SEVENTY years ago, the then small educated public read Darwin's "Origin of Species" with such avidity that its first edition of 1250 copies was sold out on the day of publication For twenty years from that date, biology, because of its obvious and direct bearing on the problem of man's place in Nature, was read and discussed by the general public That continued interest was in large part due to the controversial vigour and literary ability of Prof T H Huxley, but it was based on that aspect of the human mind which seeks an explanation of the apparent purposelessness of the universe and of human life with its joys and sorrows, distributed so capriciously and unfairly This interest, long continued, died away, and has never been revived But in its place has risen an interest far more widely spread and much less easily understood, in those modern developments of physics which depend on the relativity and quantum theories

That modern physics should have excited such popular enthusiasm is due to the literary artistry of Sir James Jeans and Sir Arthur Eddington They have explained, in simple language, results which can only be reached through that particular form of logic which is mathematics But the climax to which this interest has risen since Eddington accepted the Principle of Indeterminacy, and as a corollary passed on to human behaviour and 'free will', shows that it rests on the same basis as the earlier vogue of biology, on religious 'instincts' But, in that mathematicians are animals and that their technique of thought is in fact a phenomenon which falls within the scope of biology in its wide sense, it is certain that there must soon follow an appreciation of the human interest of the philosophical aspects of biology These exist largely in the old controversy between vitalists and mechanists in the new form which it has received from Dr J S Haldane and General Smuts In the book under review, Prof Hogben makes an ardent onslaught on these two writers, with sallies against many another biologist and minor campaigns against Whitehead and Eddington

Prof Hogben's point of view is that no biologist now claims, or will for generations, if ever, be able to claim, that all the phenomena of living things can receive a physico-chemical explanation, but that the only methods which will help to an understanding of the nature of living matter are in their nature identical with those which have proved so successful in the physical sciences He adduces the work of A V Hill and Meyerhoff in illustration of the extent to which the experimental methods of physicists and chemists, with all the fundamental ideas from which these methods arise, can be carried when they are applied to the vastly complex but relatively simple problem of the activities of an isolated but living muscle ' Through that work we have come near to establishing a balance sheet of the energy exchanges which go on in a specific tissue, and have found

no reasons for introducing any conceptions which are foreign to physics or chemistry

Prof Hogben then passes on to an examination of our knowledge of heredity We are entirely ignorant of the nature of the mechanism which determines the course of development of an animal The experimental embryologists have sometimes localised that part of the embryo which, by its presence, initiates and controls the appearance of other parts but of the nature of its influence, whether it depends on the diffusion of chemical substances, on changes in the surface of cells resulting from contacts, or on the establishment of differences of electrical potential, we know nothing There are, indeed, few phenomena of living matter less likely to be expressible in physico-chemical terms than that of hereditary resemblances and differences

Yet by methods which do not differ, except in their form, from those of students of physical science, it has become possible to analyse the varied results of breeding so successfully that a theory has been built up which enables the results of definite breeding experiments to be predicted The prediction is a statistical one, but so are all chemical predictions Prof Hogben gives an admirable account of the evidence and the mode of reasoning which has enabled Prof T H Morgan to establish the theory of the gene, the view that the things which determine the course of development of animals which, when adult, show mutations, are discrete particles, self-reproducing, arranged in a definite linear order in the chromosomes

There remains, however, one field of biology which is still being investigated by methods involving conceptions totally unlike those of the physical sciences The field of the psychologists, conscious behaviour, is still investigated by introspective methods yielding evidence valid only to the experimenter, and interpreted in terms of memory and preferences The school of Behaviourists endeavoured to examine these phenomena by methods less unlike those of chemists, without securing general acceptance for their ideas and methods, but during the past few years the conditioned reflex method of Pavlov has for the first time enabled us to examine the behaviour of a dog, in circumstances which in ourselves would involve consciousness, by methods which do not differ in their fundamental character from those used in ordinary physiological experiment, and are capable of wide extension to other animals The results which have already been reached by Prof Pavlov's own school are of the utmost importance and show that part, at any rate, of the most secure redoubt of the vitalist is open to attack

Prof Hogben is a purist To him no theory can be science unless it can be subjected to experimental substantiation All else, if we understand him right, though it may be true, is not science but some other branch of learning In Prof Hogben's opinion, the characteristic features of scientific theories are that they are established on the basis of evidence which can at any time be reproduced and is accepted by all those who enter into the discussion The discussion itself pays no attention to ethical implications, and is so conducted that personal idiosyncrasies play no part It lies, in the author's phrase, in "the Public world"

But outside this, there are series of private worlds of æsthetics, religion, and philosophy, and between these no agreement can arise by public discussion, because the evidence valid for one man may justifiably not be accepted by another, and each man's view will be determined by his individual peculiarities

Prof Hogben's book should be read by all students of biology for its exposition of a point of view, and for its penetrating criticism of some current biological conceptions It is, as a whole, brilliantly written contains much wit, and some facetiousness, but is badly constructed, containing much repetition It is, indeed, not that organised whole, a work of art D M S W

De Generatione

Early Theories of Sexual Generation By Dr F J Cole Pp x + 230 + 10 plates (Oxford Clarendon Press, London Oxford University Press, 1930) 15*s* net

THIS interesting essay is one of the relaxations that Prof F J Cole has allowed himself in the course of his labours on a "History of Zoology", and we cannot but hope that he may make yet other diversions of a similar nature, provided, of course, that the progress of the *magnum opus* is not unduly delayed Sexual generation is a subject that the inquisitive mind has always been prone to play with, and thus the history is often very picturesque, even grotesquely so This is well illustrated by the persistence with which observers, who should have known better, discerned and designed within the spermatozoon the lineaments of a fœtus

One is glad to find that Leeuwenhoek remains the discoverer of spermatozoa (about 1677), neither Huygens nor Hartsoeker having any share in the honour Mr Ham, of whom Leeuwenhoek speaks, may have assisted but he did not publish Dr Clifford Dobell, who furnishes a translation of Leeuwenhoek's historic letter, points out that it has been through a misinterpretation of words that Haller, with others after him, spoke of Hooke as demonstrating spermatozoa to Charles II's command The minute motile things he demonstrated to the King were infusorians There is often something delightful in the words used by the pioneers thus in the semen of a ram the spermatozoa were seen "moving forwards in a troop with great gravity like a flock of sheep" We know that hundreds of typical spermatozoa may readily move about without jostling in a drop of fluid suspended from the head of a pin, and Leeuwenhoek says, 'I judge a million of them would not equal in size a large grain of sand' As to shape, he compared a human spermatozoon to "a small earth nut with a long tail, and adds "I have sometimes fancied that I could even discern different parts in the bodies of these animalcules but forasmuch as I have not always been able to do so, I will say no more' Later on as Dalyell puts it we descend from the observations of Leeuwenhoek to those of Buffon, and the bathos was reached by Pouchet, who described the alimentary apparatus of the spermatozoon Even within the last hundred years Carus described the œsophagus, stomach, and intestine of the cephalopod spermatophore, and was not the great Kölliker trapped like others into regarding the discharged hectocotylus arm as a complete male animal Very shrewd was the suggestion of Treviranus, that spermatozoa were comparable to "animal pollen', but it was not until about 1841 that Kölliker gave the death blow to the widespread theory that they were parasitic vermiculi "It took over a hundred and sixty years of research to establish that the spermatozoa were not homunculi or parasites with a complex organisation, but tissue elements of the animals in which they were found'

The *pièce de resistance* in Prof Cole's fascinating book is the story of the preformation doctrine, for the first time told in a complete fashion, with the historical scenery that is needed to give a true perspective We are shown that the preformation doctrine, an outgrowth of the Mosaic cosmogony, propounded the extraordinary view that there was no generation in Nature, but only the unfolding of a diminishing series of germs created at the beginning of the world Inside the insect's cocoon there is a preformed insect, only requiring to be unfolded—born but not made At earlier stages there is similar preformation, though it may be too small or transparent to be seen Gaps were filled "by the mendacity of some and the mistaken credulity of others"

How was it that "for over a century the most popular theory of generation involved a denial that such a process actually existed, or that it afforded any scope for original research"? Partly because preformationism fitted in well with a wooden creationism, partly because microscopic research still remained very difficult, partly because attention was preoccupied with a few objects, like the pupa in its case, which suggested a preformed miniature organism, or even, in rare curiosities like *Miastor*, one generation inside another But the main reason for the vicious parenthesis was really that in spite of reawakeners like Vesalius, the scientific mood was still more than half asleep as regards the problems of development What a fine contempt there is in Von Baer's remark (1837) in regard to the theory of *emboîtement* "Although this hypothesis borders on the insane, it has been advocated by very distinguished naturalists, and it affords a striking example of the aberrations into which one can fall if we systematically follow assumption rather than observation

Prof Cole gives the most scholarly account of preformationism that has yet been published it is so perfect that we do not think that any more detail, or setting, or interpretation need be looked for in days to come, especially since the long drawn out absurdity, whether with or without *emboîtement* or encasement, bordered closely on the pathological Of course he distinguishes the *ovism* of Swammerdam, Malpighi, Haller, Spallanzani and Bonnet, who located the preformed fœtus in the ovum, from the *animalculism, spermatism*, or *vermiculism* of, say, Leeuwenhoek, who championed the spermatozoon and to these two forms he adds a third, represented by Prévost, Dumas, and Rolando, who suggested that an imperfectly preformed embryo in the egg or in the sperm is completed by epigenesis But this suggests a cross division of theories

Prof Cole is such a fine historian that we occasionally get a suggestion that his qualities in this direction outrun his biological acumen Thus he arranges the various theories of generation prevalent in the seventeenth and eighteenth centuries as (1) pangenesis, (2) precipitation, (3) semin-

ism, (4) preformation (*Vorbildung*), (5) epigenesis (*Nachbildung*), and (6) panspermy, but this does not strike us as a convincing grouping. Thus, 'precipitation' is a very different *kind* of theory from 'panspermy', which is practically the same as abiogenesis. Again, we do not feel at all convinced that Darwin resuscitated the ancient theory of pangenesis, which accounted for the germ by assuming contributions from all parts of the body. For Darwin recognised the existence of the *sexual elements*, and evidently thought of them not only as receiving gemmules from their bearer's body, but also as receiving them in a dormant state from preceding generations (see 'Variation of Animals and Plants', 1868, vol. 2, p. 402, etc.).

Then again, is there not a risk of confusion in the learned author's suggestion that modern advances are leading us behind a descriptive epigenetic embryography to an explanatory preformationist embryology? For modern genetics is so utterly different from the old preformationism that the use of the old word is almost perverse. Moreover, even the general idea is on another plane, for we think of developmental initiatives liberating other initiatives in a long succession, not of simultaneity of original equipment.

The chapter on fertilisation is a fine piece of work, but its very excellence leads us to suggest for another edition that all these stories of fumbling tentatives would be more educative if they ended, ever so shortly, in a statement of the modern position. Thus we get so much intrigued with early theories of like begetting like that we almost demand Weismann's continuity of the germ plasm, and so with fertilisation. But the book is none the less deserving of being called masterly.

J. A. T.

In Mesopotamia during the War

Loyalties: Mesopotamia 1914–1917, a Personal and Historical Record. By Lieut.-Col. Sir Arnold T. Wilson. Pp. xxxvi + 340 + 28 plates. (London: Oxford University Press, 1930.) 25s. net.

CONSIDERING the never ending spate of books dealing with the multitudinous aspects of the Great War, world wide as it was, with a story in every continent, it is curious to reflect that the struggle in Mesopotamia has had until now no competent historian. Sir Arnold Wilson, who lived and moved and had his being in those epic years in the Middle East, is peculiarly fitted to describe the moving pageant of the War in that theatre, since he, above all others, had the responsibility of making effective the civil administration that step by step followed in the wake of the military arm. By training a soldier—and a distinguished one—by race and instinct an administrator of insight and vision, he is admirably qualified to make clear "a tale of great deeds by land and river, sea and air, of suffering and endurance, and faithfulness unto death on both sides, in pursuit of objects dimly seen, and of aims but darkly understood."

It is the particular genius of the English to be able to implant and nourish the seeds of political organisation and of the broad principles of tolerant governance in whatever spheres they are placed, and Sir Arnold's thesis is, in effect, a dissertation on the creation of the mechanism of administration in a land newly conquered, and amongst a people indifferent, if not at first actively hostile. To readers of NATURE the characteristic impact on affairs of botanists, geologists, bacteriologists, entomologists, hygienists, and chemists is at least equal in interest to the story of the military occupation and the subsequent pacification and orderly organisation. Sir Arnold was quick to see the importance of enlisting every scientific arm into the general service, and hard on the heels of the purely political officer followed men, often with difficulty extricated from the ranks of the forces, whose special aptitudes fitted them for the even more urgent scientific functions in this field. Sanitation, water purification, attack on parasites, bacteriological investigations, geological surveys, siting of quarries, and innumerable other problems of first importance for the health and well being of the great armies in Mesopotamia, were solved by the efforts of this devoted band.

Of the darker side of the campaign the author has, in a characteristically reticent way, conveyed a sufficiently serious message to the nation in particular and to civilisation in general. Mismanagement unhappily is common to all human effort, but never was it more apparent than in the breakdown of the medical service in Mesopotamia, though Sir Arnold pays a notable tribute to the services of Dr. (now Sir William) Willcox in bringing the resources of science to bear on delicate problems of diagnosis and prophylaxis. Quoting from the Report of the Commission in 1917:

"The medical provision ... was from the beginning insufficient. ... By reason of the continuance of this insufficiency there was a lamentable breakdown in the care of the sick and wounded. ... The defects of medical provision caused avoidable suffering to the sick and wounded, and during the breakdown of the winter of 1915–16 this suffering was most lamentably severe."

Even worse is the harrowing story of the survivors of Kut "The scene at Baghaila was one of anguish and misery The march itself (from Kut) was a nightmare The Arab soldiery used sticks and whips to flog the stragglers on Some have been thrashed to death, some killed some left to be tortured by the Arab Every now and then we stopped to bury our dead" 2592 British rank and file left Kut, 1700 died in captivity Such was 'the gentlemanly' Turk, but "The General Staff in Mesopotamia discredited every report of brutality or cruelty till the bitter truth could no longer be hidden" The reviewer has purposely quoted these terrible details of the grimmer aspects of the War to direct attention to a chapter which is written with a restraint and a latent fire that render it one of the most effective exposures of a foolish tradition ever put forward

It remains finally to congratulate the author on the achievement of a living history It would be supererogatory to direct attention to the easy flow of its style, to the wealth of knowledge and sympathy enshrined in it, to the reticence of a man who feels deeply, and felt deeply, in telling and recalling its moving story It is a book that no Briton should fail to read, and in reading, to anticipate with no less interest the sequel that will deal with the later history of the War and the notable and fruitful scientific services in connexion with agricultural and mineral development, aviation, and preventive hygiene A E D

Biological Catalysts

Enzymes By Prof J B S Haldane (Monographs on Biochemistry) Pp vii + 235 (London, New York and Toronto Longmans, Green and Co, Ltd, 1930) 14*s* net

THIS book marks a new departure in the series of Monographs on Biochemistry, additions to which have appeared at intervals since its happy inauguration in 1908, for the subject has already been treated in an earlier volume of the series, Bayliss's "Nature of Enzyme Action" (1908), the last edition of which from its author's hand appeared in 1925 As the present author points out, Bayliss's book was strongly individual and it was rightly thought that an entirely new work would be better than an attempt by an alien hand to bring Bayliss up-to-date Bayliss's main thesis was that enzymes act as colloidal catalysts and combine with their substrates and other substances by adsorption, "so that the action of enzymes in general must be regarded as exerted by their surface", and a large part of his book was devoted to the support of this view In the present work this position is assumed almost without discussion, though it is carefully pointed out that "the assumption that an enzyme molecule activates only one substrate molecule at a time has worked remarkably well"

In the new book, the influence on enzyme action of such factors as enzyme concentration, hydrogen ion concentration, temperature, radiation, and the union of the enzyme with its substrate and other compounds is first considered Then follows a chapter on the course of enzymatic reactions and its mathematical theory, treated with a profusion of mathematics which implies a high, and we hope well deserved, compliment to the attainments of the readers of the book Interesting chapters follow on specificity, coenzymes and other adjuvants, the 'poisoning' of enzymes, and the purification of enzymes, and the work is concluded by a chapter on the theory of enzyme action and classification

Throughout the book a wealth of examples is brought forward, which fully justifies the author's reputation for an encyclopædic knowledge of the literature, but sometimes leaves the reader a little breathless A number of tables are included, in which a great mass of information is usefully summarised

The author, perhaps wisely, avoids generalisations, but it can be gleaned from his pages that he regards enzymes, defined as soluble, colloidal, organic catalysts produced by living organisms, as capable of combining with their substrates, owing to the chemical structure of the latter, and also with at least one of the products of the reaction catalysed In this combination the substrate molecules do not, in general, cover the whole surface of the enzyme The substrate in this situation requires the addition of less than the usual amount of energy increment to enable it to undergo the chemical change in question The reason for this is not definitely known, but the author makes an interesting suggestion, and Quastel's theory of active centres provides another The fundamental question as to the exact structure which renders an enzyme capable of exerting its specific effects has not yet been answered

Biochemists have every reason to be grateful to the author for the abundance of material which he has put before them, and for the careful and logical way in which he has treated it

ARTHUR HARDEN

Birds of Africa and Asia

(1) *Nicoll's Birds of Egypt* By Colonel R Meinertzhagen Published under the Authority of the Egyptian Government Vol 1 Pp xvi + 348 + 19 plates Vol 2 Pp 349-700 + 19 plates (London Hugh Rees, Ltd , 1930) 30*s*

(2) *The Game Birds of India, Burma and Ceylon* By E C Stuart Baker (Published by the Bombay Natural History Society) Vol 3 *Pheasants and Bustard Quail* Pp x + 341 + 20 plates (London John Bale, Sons and Danielsson, Ltd , 1930) 42*s* net

(3) *A Handbook of the Birds of Eastern China (Chihli, Shantung, Kiangsu, Anhwei, Kiangsi, Chekiang, Fohkien and Kwangtung Provinces)* By J D D La Touche Part 5 *Containing Families Motacillidæ, Alaudidæ, Zosteropidæ, Nectariniidæ, Dicæidæ, Pittidæ and Eurylaimidæ* Pp 399 500 + xx + 2 plates (London Taylor and Francis, 1930) 7*s* 6*d* net

(4) *Coloured Plates of the Birds of Ceylon* By G M Henry With a Short Description of each Bird by W E Wait (Published by the Ceylon Government) Part 3 Pp iii + 16 + 16 plates (Colombo Colombo Museum , London Dulau and Co , Ltd , 1930) 30*s*

(5) *Systema Avium Æthiopicarum a Systematic List of the Birds of the Ethiopian Region* By William Lutley Sclater Prepared in conjunction with Special Committees of the British and American Ornithologists' Unions Part 2 Pp iii + 305 922 (London Taylor and Francis, 1930) 21*s*

THE titles above are evidence of the progress being made towards a conspectus of the world's avifauna For one country or region after another, books are steadily appearing which collate, for their respective areas, information which was previously either unavailable or else widely scattered in the ornithological journals in some cases they break fresh ground, while in others they replace older works now out-of-date The particular volumes here to be discussed range from Africa to the Far East

(1) Pride of place must be given to the work on Egyptian birds which Col Meinertzhagen has compiled upon foundations laid by the late Michael Nicoll Unlike the others mentioned, it is issued complete—in two volumes simultaneously published It is also, both in form and content, one of the most admirable bird-books of recent years The volumes are of sumptuous size, well bound, and printed in a manner which leaves nothing to be desired In addition to numerous text-figures and three useful maps, there is a series of photogravures and very beautifully coloured plates excellently reproduced In these circumstances, thirty shillings for the two volumes together must be regarded as an extraordinarily low price

The fine production is justified by the quality of the subject matter Nicoll had been assistant director of the Zoological Gardens at Giza for eighteen years when ill health compelled him to retire in 1924 and led to his death in the following year, at the age of forty five years During that period he had published a " Handlist of the Birds of Egypt " (1919) and had amassed much material for this larger work His task has now been very ably completed by Col Meinertzhagen, who has not only cast the whole into proper form, but also has supplemented the information from his own field experience in Egypt and by further study of the specimens available in Nicoll s collection and elsewhere The result must certainly rank as a very valuable addition to ornithological literature, and it well fulfils the author's desire to provide a worthy memorial to his friend

The bulk of the work naturally consists of accounts of the individual species , these are systematically arranged and provided with useful identification keys A series of appendices tabulates the birds according to their status—the residents, the few summer visitors coming from the south to breed, and the very numerous species from the north and north east that visit Egypt on passage or for the winter

Unlike many authors of such works, however, Col Meinertzhagen is not content with merely systematic treatment of his subject He rightly asserts the necessity for using the data in some approach to general biological problems relevant to the area, and he proceeds to give practical effect to this view in several introductory chapters of much interest The first volume opens with accounts of the physical geography and the geology of the country There follows a brief general dissertation on the theory of evolution, but this does not seem altogether necessary and scarcely does justice to the complexity of that subject The author is on firmer ground when he discusses the origin of life in Egypt There are three principal types of country to be considered The oases, first, are regarded as the relics of a former rain-watered area of wide extent desert, secondly, has largely supervened , and, thirdly, the Nile valley and delta are of still more recent origin In the first and third of these habitats, the

avifauna is mainly of Palæarctic type, but with a strong tropical flavour due to species which have either remained from pre glacial times or have come from the south more recently with the development of the Nile valley On the other hand, the true desert avifauna is considered to have spread from the east

The chapter dealing with migration to, from, and in Egypt is of especial value and raises many points of general interest It includes a section on the difficult questions of sex and age in relation to migration, and of the possible influence of moult Mr R E Moreau contributes a section to this chapter on migration, and also a well illustrated chapter on the birds of ancient Egypt as known from inscriptions, mural decorations, and mummified specimens Finally, there is a chapter in which Col Meinertzhagen deals with practical questions of bird protection in Egypt

(2) Mr Stuart Baker's third volume on Indian game birds, dealing with the pheasants and bustard quail, follows its predecessors after an interval of nine years, a delay possibly due to the author's preoccupation with his greater work on 'The Fauna of British India', of which the eighth and final volume has also recently appeared The present book aims, on one hand at giving a scientific review of the birds which form its subject, and on the other, at providing a useful guide to sportsmen It admirably fulfils both purposes, as was to be expected from an author who is not only a recognised authority on Indian ornithology but also a well known game shot The volume is handsomely made up and well illustrated

(3) With the fifth part of his handbook, Mr La Touche completes his first volume and also his account of the passerine birds of eastern China This work is on a less ambitious scale than those mentioned above, containing, for example, no figures of the species, but it gives adequate descriptions of the birds, as well as accounts of their distribution in the region, and it should serve a useful purpose

(4) Mr Henry's work, on the other hand, consists almost entirely of illustrations The sixteen plates from his brush are of a high order of merit and have been excellently reproduced in colour The object has been to depict a series of birds characteristic of Ceylon The majority of the species or sub species selected are indeed peculiar to the island To each plate there is a brief annotation by Mr W E Wait, to whose "Manual of the Birds of Ceylon" (1925) this work may in some sense be regarded as a pictorial supplement

(5) Mr Sclater's "Systema" is a work of reference in its severest form—invaluable to serious students dealing with African ornithology, but necessarily making no general appeal It is a classified catalogue of the birds of the region, the volume now before us dealing with the passerine birds and comprising more than four thousand forms The author is to be congratulated on the completion of a most laborious task His work bears the stamp of authority and will serve as a base line for further systematic work for a long time to come

It is worthy of note that both Col Meinertzhagen's and Mr Henry's works are published under the auspices of the governments of the countries concerned The same applies to Mr David Bannerman's "Birds of Tropical West Africa", of which the first volume was recently reviewed in these pages Without this support, the publication of such books would often be impossible

X-Rays and their Applications

(1) *X ray Crystallography* By R W James (Methuen's Monographs on Physical Subjects) Pp vii + 88 (London Methuen and Co, Ltd, 1930) 2*s* 6*d* net

(3) *Les applications des rayons X physique, chimie, metallurgie* Par Dr J J Trillat (Recueil des Conférences Rapports de documentation sur la Physique) Pp 298 + 16 planches (Paris Les Presses universitaires de France, 1930) 85 francs

(4) *X-ray Technology the Production, Measurement and Applications of X rays* By Dr H M Terrill and Dr C T Ulrey Pp viii + 256 (London Chapman and Hall, Ltd, 1930) 21*s* net

(5) *Handbuch der Experimentalphysik* Herausgegeben von W Wien und F Harms Unter Mitarbeit von H Lenz Band 24, Teil 1 *Allgemeine Physik der Röntgenstrahlen* Von Fritz Kirchner Pp x + 548 (Leipzig Akademische Verlagsgesellschaft m b H, 1930) 55 gold marks

RÖNTGEN'S discovery of X rays at the end of the year 1895 began a new era in the history of scientific investigation Few discoveries have so speedily been followed by important benefits to mankind in connexion with medicine and surgery, and by equally important theoretical advances It is no exaggeration to say that our present knowledge of the structure of the atom dates from 1895,

for not only did the X-rays provide a convenient means of producing ionisation in a gas, but also by their penetrating power they suggested that search for other penetrating radiations which resulted in the discovery of radioactivity. Yet on looking back it seems somewhat strange that there should have been such a long interval—about seventeen years—between the first discovery of X-rays and the introduction of a crystal as a three-dimensional diffraction grating for the analysis of the rays. We may recall the fact that there was a slightly longer interval a century earlier between the invention of the voltaic cell and the discovery of the magnetic action of the current by Oersted. To the intuition of von Laue (1912) we owe the X-ray spectrograph and the marvellous developments which have followed from its introduction by the Braggs and its improvement by other workers.

(1) Mr. R. W. James, who has had experience in Prof. W. L. Bragg's laboratory in the University of Manchester, has written a very good monograph on X-ray crystallography. He has dealt with general methods rather than with their application to particular cases, and in consequence his little book should serve as a useful introduction to the standard works listed in the bibliography. "It is now clear that the type of regular arrangement formerly associated only with definite crystals is characteristic of all true solids, and that the study of crystal structure is really the study of the architecture of matter in the solid state." He begins with a description of crystal form and the space lattice, and then considers the crystal lattice as a diffraction grating. The longest chapter is that on the symmetry of crystals and its determination by means of X-rays.

Natural crystals may be regarded as mosaics of more or less perfect blocks, which, although nearly parallel, may vary in orientation over a small range of angles. If suitable material is available, the size of the unit cell can be determined and the space lattice investigated by examining a large number of spectra and noticing systematic absences of spectra of a general type. It is usually possible to determine also the space group, the scaffolding of symmetry planes and axes upon which the structure is built.

To find the exact positions of the atoms it is necessary to study the intensities of the X-ray spectra, and the extremely interesting chapter on this subject reveals some of the difficult problems with which the investigator has had to deal in interpreting his results and the skill with which these questions have been attacked. "Each crystal is a separate problem, and the success obtained in determining its structure depends largely on the skill and experience of the worker."

In the final chapter, on types of crystal structure, the author considers some of the more noteworthy results of crystal analysis, dealing in particular with simple metallic and ionic crystals, complex ions, the silicates, and lastly, molecular and organic crystals.

(2) Dr. Jean Thibaud has carried out successful pioneer work on the properties of the soft X-rays, having designed a grating spectrograph by means of which he has helped to bridge the gap between the ordinary X-ray region and the ultra-violet. If the grating is calibrated by means of a line in the visible or ultra-violet spectrum, the wavelengths of X-rays can be determined and the grating constant of a crystal can be deduced. Thus the measurements provide an independent estimate of Avogadro's constant and the fundamental electron charge.

In the volume before us, Dr. Thibaud has provided a compact and lucid account of the theory and the applications of X-rays. The book is divided into four parts, the first dealing with X-rays considered as electromagnetic radiations, the second with X-rays as quanta, the third with the technique of the rays and their practical applications, and the last part containing a short account of related rays such as the gamma rays and the 'waves' of L. de Broglie. The volume forms an admirable introduction to the science of X-rays, which, as the author points out, has led not only to deep philosophical speculations as to the structure of matter but also to a long series of technical and industrial applications.

(3) Dr. J. J. Trillat has written a comprehensive treatise on the applications of X-rays in physics, chemistry, and metallurgy, special attention being paid to the more recent developments. The book is divided into two parts of unequal length. In the first part, extending to about one hundred pages, the author deals with generalities necessary for understanding the following chapters. The methods of producing X-rays are discussed at length, and a detailed description is given of the apparatus and methods employed in X-ray spectrography.

In the second part of his work, Dr. Trillat describes the various applications of X-rays in the domain of physical chemistry and in industry. The most significant feature of this part of the book is the great development which has taken place in the application of the rays to the study of organic compounds, including colloidal sub-

stances, cellulose and its derivatives, caoutchouc, resins, gelatins, etc The sixteen plates which illustrate the book are very striking, and show the great advances which have been made in recent years in the technique of the subject

(4) In the volume by Drs Terrill and Ulrey the practical rather than the theoretical aspects of X ray measurements are presented Many of the problems discussed are common to all X-ray laboratories, but particular attention has been given to the quantitative measurements involved in X-ray therapy and in industrial applications The subject has advanced to such a stage that a considerable portion of the contents may be pro perly classified as X ray engineering The book is specially valuable for the practical hints which it contains regarding the construction and use of apparatus, and mention may be made of the descriptions of various forms of tubes and of the precautions to be observed in exhausting them so that they may be sealed off from the pump

The temptation to quote interesting statements is great, but only a few can be given In the highest vacuum attainable to day (about 10^{-4} bar) there are still more than a 'billion' (10^9) molecules in each cubic centimetre A very small part of the energy of cathode rays, only one or two tenths of one per cent, comes out of the target in the form of X-rays Lenard ray tubes have recently been constructed with thin glass windows of about 0 001 cm thickness which can still support atmo spheric pressure The emergent rays can thus be produced at lower voltages than when windows of denser metals are used This book should be of great service in the laboratory

(5) The large volume on Rontgen rays in the "Handbuch der Experimentalphysik" is written by Dr Kirchner, of Munich, and includes the general physics of the phenomena associated with the rays, but not the subjects of X ray spectroscopy and crystal analysis, which are treated in separate volumes The book falls into three parts, the first dealing with the production and measurement of the rays, the second with electron emission produced by the rays and the accompanying phenomena, and the third with the scattering of the rays We have here a very complete account of the subjects treated, including the earlier as well as the more recent researches

Of special interest are the chapters touching upon the Compton effect, in which a quantum of primary radiation colliding with a *free* electron recoils from the impact with diminished energy and therefore lower frequency It is no longer possible to doubt the reality of this effect, now confirmed by so many investigations, and in consequence the classical electromagnetic theory can no longer be considered adequate for the explanation of the relations between electrons and radiation Some form of the quantum theory must necessarily be accepted,

H S Allen

Sound and its Uses

(1) *A Textbook of Sound being an Account of the Physics of Vibrations with special reference to recent Theoretical and Technical Developments* By Dr A B Wood Pp xiv + 519 (London G Bell and Sons, Ltd , 1930) 25*s* net

(2) *Sound Waves and their Uses Six Lectures delivered before a "Juvenile Auditory" under the auspices of the Royal Institution, Christmas 1928* By Dr Alexander Wood Pp x + 152 (London, Glasgow and Bombay Blackie and Son, Ltd , 1930) 7*s* 6*d* net

(1) IN reading acoustical literature, it is, at times, difficult to avoid an impression that the publication of Rayleigh's masterly treatise, 'The Theory of Sound", tended to exert a harmful influence on the subject as a whole Thus, in the preface of the latest text book on sound, we find its author writing "The change which has taken place during the past ten or twenty years in the study of mechanical vibration and sound is my excuse for writing this book when such treatises as those of Rayleigh and Lamb already exist" Since a complete physical theory of a phenomenon is only obtained when mathematical and experi mental work both yield the same quantitative results, the two treatises referred to should never be regarded as treatises on sound, but only as treatises on the *theory* of sound The justification for Dr Wood's book is not merely his description of the recent advances in sound, but rather his skill in giving equal importance to experiment and to theory

Until quite recently, sound suffered from the fact that its mathematical theories had far out stripped experimental technique, which had to wait for the development of the thermionic valve and those electrical instruments of similar delicacy the applications of which are so well described in the present volume Before their appearance, the mathematicians had become too impatient, as can be well illustrated by a particular problem—that of the struck string Helmholtz gave two theoreti cal treatments which were never tested experi mentally Rayleigh felt justified in writing of

them, "Helmholtz has obtained a solution representing all the essential features of the case" Now it is no exaggeration to say that, to correct this statement, "none of" would have to be substituted for "all" The validity of any particular theory of the struck string is of little importance, but it is surely of fundamental importance to realise that quantitative agreement between experiment and theory is an essential test of the validity of any theory The appearance of a correct piece of mathematics in Rayleigh's "Sound" is no guarantee that it necessarily represents Nature's behaviour in the particular phenomenon concerned

Dr Wood's book is thoroughly modern in outlook and covers all branches of the subject with the exception of musical instruments Such subjects as relaxation oscillations and power considerations, which are not found elsewhere, receive adequate attention here Even so classical a subject as the transverse vibrations of strings is thoroughly revitalised by a discussion of the electromagnetic means of excitation, the Dye sonometer capable of measuring or adjusting an electrical frequency with an accuracy of 1 in 1000 over a considerable range, and the latest Einthoven string galvanometer with its string only 1 mm long, stretched in a high vacuum (less than 10^{-3} mm of mercury), and tunable to radio frequencies of the order 3×10^5 cycles per second In the discussion of sources of alternating current, no mention is made of the various gramophone records available for this purpose It is a pleasure to note that in the chapter on technical applications, including the measurement of distance by sound, acoustics of buildings, the gramophone, sound films, and alternating power transmission by the Constantinesco system, four pages are devoted to the problem of noise reduction

Not only is this text-book the best so far produced on its subject in any language, but also, in the skilful blending of theory and experiment and in the careful statement of assumed initial and boundary conditions and factors omitted from a particular treatment, it forms a model of the ideal text book

(2) Dr A Wood's book founded on the Royal Institution 1928 Christmas Lectures is a popular, well illustrated account of sound waves and some of their uses The first lecture on waves introduces no new experiments, and Fig 6 is quite Victorian In the course of the second lecture, dealing mainly with signalling in air and water, data are given of the efficiency of various sound sources, from which it appears that the human voice with an efficiency of only one per cent is one of the best The remaining lectures deal with musical sounds, sound analysis, hearing, and sound recording and reproduction At the end of each chapter is an extensive bibliography, that at the end of Chap vi includes references which show that the gramophone sound-box reproduced as typical in Fig 129 is out-of-date

Although the work is an attractive presentation of interesting facts, it gives nothing more than the facts The uses of sound waves dealt with are chiefly those which would foster the impression that science is 'the hewer of wood and drawer of water' for humanity Too little attention is given to the most important use of sound in the rapid communication of thought, and may we not also include the effect produced upon music lovers by a symphony or a string quartet as an important use of sound? In so hackneyed a subject for popular lecturing, one would have liked to see the facts of the lectures used as propaganda for the cause of pure science, or as a means of demonstrating scientific method, science as a way of thinking and reasoning The discussion of the silent zone in the second lecture, for example, would have served admirably for this latter purpose The publication of such a book as this, a collection of facts, without an index, is unforgivable W H GEORGE

Line and Band Spectra.

(1) *The Structure of Line Spectra* By Prof Linus Pauling and Prof Samuel Goudsmit (International Series in Physics) Pp x + 263 (New York McGraw Hill Book Co, Inc, London McGraw Hill Publishing Co, Ltd, 1930) 17*s* 6*d* net

(2) *Band Spectra and Molecular Structure* By Dr R de L Kronig Pp x + 163 (Cambridge At the University Press, 1930) 10*s* 6*d* net

BOOKS dealing with modern physics can often be divided into two classes Into one category fall those which are conscious throughout of the reader's infirmities (real or imaginary), while in the other will be found those works—full of intellectual honesty—which face the facts and leave the aspirant to strike out for himself as best he may, even though he is certain to meet with heavy weather Such a classification is reasonably well illustrated by the two books before us, into the first group goes the volume by Profs Pauling and Goudsmit, and into the second that by Dr Kronig

(1) "The Structure of Line Spectra" is true to its title, in that the atom receives nearly all the attention The authors frankly state their prefer-

ence for the vector model, and base the whole of their treatment upon it Much space in the early part of the book is occupied by discussions about orbits (in Bohr's sense), followed by the conventional introduction to the simplest application of the wave equation This being so, it is a little difficult to see why we might not have been spared the orbits in their unregenerate guise and thus create more room for enlarging the section on quantum mechanics As it is, the stationary states of the hydrogen atom and the equations describing them on the older quantum theory appear to serve no useful purpose

The following chapters deal adequately with the usual applications of the vector model to alkali-like atoms (with the appropriate extensions), intensities, the Pauli *Verbot*, hyperfine structure, and nuclear moment A decidedly good account of Hund's work on the magnetic moments of ions of the rare earths and the causes of the failure of the theory for the transitional elements will be found in the last chapter This subject is exercising many minds at the present stage of development of spectroscopic conceptions in relation to chemical statics

Taken on the whole, the volume should find a place on the shelves of a certain type of worker there may be more such workers in the United States than in Great Britain One sympathises with the authors' objects in writing the book, but it tends to fall between two stools, in being a trifle too specialised for the able honours man in his last year, and yet too staid for the research worker who has any hopes of possessing or acquiring a *flair* He will go to the sources themselves, cost what it may

(2) Dr Kronig's "Band Spectra and Molecular Structure" consists of a series of lectures given at Trinity College, Cambridge, in 1929 Those who had the privilege of hearing them will recognise in the printed page the masterly grasp and rigour of the author He never for one moment permits himself to be deflected from the fundamentally theoretical nature of his subject, though a few kindly asterisks warn the weaker brethren when they may—with detriment it is true, but without abandoning salvation—omit paragraphs dealing, for the most part, with purely mathematical machinery In a word, it approaches the ideal book, and one wishes that there were more of it

The spectroscopist, in dealing with the molecule, has evolved a method whereby he is able to picture his assemblage as having three kinds of energy levels —(*a*) electronic, in which the nuclei are treated as fixed centres of force at a certain distance ρ apart, (*b*) vibrational, in which ρ is no longer a constant, so that the nuclei move to and fro along a straight line, and (*c*) rotational, in which the nuclei can take up any position in space The mathematical justification for classifying these energy levels by means of quantum numbers demands, as might be expected, the neglect of small terms in the Hamiltonian H, where H is a differential operator in the wave equation $(H - W)\psi = 0$

The application of perturbation theory leads to a knowledge of the influence of these rejected terms, that is, an understanding of the rotational distortion of spin multiplets and the so called Λ doubling in rotational levels The minor terms are also of importance for the phenomenon of pre dissociation

A chapter on the macroscopic properties of molecular gases is very welcome, in which Dr Kronig discusses the modern views on magnetic susceptibilities and specific heats Finally, some space is devoted to the newer theories of chemical combination, with special reference to homopolar molecules

If a couple of very minor criticisms may be made, it is only with the object of making the book quite indispensable One is that in a future edition the bibliography might be brought as up to-date as it is possible to bring it (the present one ends at November 1929, which is a somewhat remote date as physicists count time in these days for a work published in October 1930), and the other that an author's index should be provided, particularly to references in the body of the text One not infrequently knows the name of an investigator without being quite sure what precisely he investigated Dr Kronig's volume is the obvious place in which to look, and to find massive learning combined with great lucidity

F I G R

Qualitative and Quantitative Analysis

(1) *Analytical Chemistry* Based on the German Text of Prof F P Treadwell Translated and revised by Prof William T Hall Vol 1 *Qualitative Analysis* Seventh English edition, revised Pp ix + 610 (New York John Wiley and Sons, Inc, London Chapman and Hall, Ltd, 1930) 23*s* net

(2) *Select Methods of Metallurgical Analysis* By Dr W A Naish and J. E Clennell Pp xii + 495 + 9 plates (London Chapman and Hall, Ltd, 1929) 30*s* net

(1) ALTHOUGH Treadwell's work is now a classic, there have been some changes and improvements in the present edition which seem to call for description There is, first, a concise but clear account of the fundamental physico-

chemical theories, with examples of their applications to analytical chemistry In the section on electrode potentials the American system of signs is adopted It is the opposite of that used in Europe, and although each system has advantages in particular aspects of the matter, it is desirable that a common system should be reached by agreement In the numerical tables there is, of course, the additional complication of the definition of the normal state

The solubility product relation, with useful numerical examples, is discussed in a critical manner on pp 21 3, and a comprehensive table of solubility products, together with the solubilities in pure water calculated from these values, is given The American editor points out that the values in the literature are not in good agreement, but it is evident that he has used a good deal of judgment in the selection of the values which appear in his table

On pp 461 2, however, reference is made to another table of solubility values given in a recent German edition of Fresenius's "Qualitative Analysis", with the remarks that "there is no mention of how the values were obtained", but that "the data given in the German text doubtless represent many hours of careful, accurate, and skilful analytical work" These values are, however, merely compiled from a part of Landolt-Bornstein's tables other than that used by the American author in the preparation of his table The differences are startling, for example, in the case of cupric sulphide, one value in Landolt-Bornstein is $3\cdot6 \times 10^{-4}$ gm /lit and another is $8\cdot7 \times 10^{-21}$ gm /lit Prof Hall considers that the lower values for the solubilities of sulphides better represent the behaviour of these substances in qualitative analysis

The preparation of reagents (in which the desirability of using solutions of known strength is emphasised) and the reactions of the more common metals and acids follow, and in the latter section (which occupies most of the book) it is satisfactory to find practically all the newer tests which seem likely to have a permanent value On p 88 there is some confusion, in the description of Ball's reagent, between nitrites and nitrates The division of the metals into groups follows the classical scheme, and there is no doubt that, with the average student, this gives very satisfactory results Alternative schemes of separation of the constituents of a group are also given, the notes on these separations being full and informative, and a most valuable feature of the book The acids are dealt with on the basis of a scheme due to Bunsen, depending on the properties of the silver and barium salts

Pages 497 567 deal with the reactions of some of the rarer metals, a subject which is becoming increasingly important in view of the extending use of these elements in industry The analyst who omits to test for elements like molybdenum, tungsten, titanium, and vanadium may overlook the most essential part of the material in his hands. The book closes with a scheme for the detection of all metallic constituents, adapted from the work of Noyes and Bray ("Qualitative Analysis for the Rare Elements", New York, 1927)

It will be seen that the new edition of Treadwell's "Qualitative Analysis" is one which, in the hands of teachers and of more advanced students, will be found of the greatest utility, and it provides a valuable work of reference For the elementary student it is, of course, too detailed, but it is suitable for students who have completed a course of intermediate standard The amount of information contained in the book is astonishingly large, and from this point of view the price, although somewhat high for the student, is reasonable

(2) In an introduction to Naish and Clennell's book, Sir Harold Carpenter points out that the work is one which will be useful to professional metallurgists, assayers, chemists, and students, principally because the methods it describes have been selected on account of their accuracy and their general suitability for the purpose in view Most of these methods have been actually tried out by the authors themselves, and this considerably enhances the value of the work, distinguishing it from so many of the often careless, expensive, and tedious compilations, with little exhibition of critical faculties on the part of the authors, which continually pour on the scientific book market, and particularly from Germany Another valuable feature of the present work is that equal prominence is given to both the rare and ordinary elements As Sir Harold Carpenter says, the majority of modern works on analysis ignore many of these elements, yet "if experimenters were to examine their specimens more frequently for the rare elements, they would probably be detected in many minerals and metallurgical products in which they are not suspected" It is within the reviewer's knowledge that vanadium in an industrial product has more than once been returned as 'copper' by chemists of considerable ability

It may be agreed, therefore, that the aims of the book are sound, and that the choice of topics is sufficiently wide to make it applicable to most metallurgical materials The only matter which calls for detailed comment is how the methods proposed by the authors are likely to work in the laboratory Chapters on mineral analysis, electrometric titrations, and spectrographic methods have been contributed by specialists, from which we may conclude that such methods are not yet in common use in the metallurgical laboratory, since otherwise they would have fallen within the experience of the main authors, who, nevertheless, consider them "to be of the greatest interest and value to metallurgical chemists" The reviewer has tested the remaining text by looking up a few problems in quantitative analysis in which he has been interested and which are not dealt with in the ordinary books In all cases, a method was described which had every appearance of reliability The details given in nearly all the descriptions reveal a familiarity with the actual methods on the part of the authors which inspires confidence

The book contains a large amount of material, well arranged and with useful cross references Qualitative analysis of the common metals and acid radicals and rare metals, preparation of solutions, sampling, selected methods for the quantitative analysis of the elements (arranged in alphabetical order with bibliographies), analysis of commercial metals, non ferrous alloys, iron and steel and ferro-alloys, ores, slags, metallurgical products (drosses, ashes, scrap, and so on), including assaying, refractory materials, and coal, are all dealt with in a very practical manner, and the chemist who follows the clear directions of the authors may hope to carry out the operations with success The book is well printed and provided with a good index It should commend itself to a large number of chemists

Chemistry of Sulphur and Selenium

A Comprehensive Treatise on Inorganic and Theoretical Chemistry By Dr J W Mellor Vol 10 *S, Se* Pp x + 958 (London, New York and Toronto Longmans, Green and Co, Ltd, 1930) 63*s* net

IT is more difficult to write an adequate review of the tenth volume of Mellor's "Comprehensive Treatise" than it was to review the earlier volumes, since the author's methods of presentation have long since become standardised and are now quite well known Indeed, an intelligent reader might hope to predict the general characteristics of the volume on sulphur and selenium by studying those on the related elements, in the same way that Mendeléeff predicted the properties of *eka-* and *dwi-*manganese from those of contiguous elements in his Periodic Classification From this point of view, the new volume is 'true to type' and presents no marked contrasts with those which have preceded it An inspection of the paragraphs dealing with subjects with which the reviewer is most familiar compels him, however, to pay a tribute of admiration to the almost uncanny way in which even the most obscure researches have been included in the author's survey

The volume on sulphur and selenium includes many interesting topics, perhaps because sulphur shows some tendency to mimic carbon by forming chains of atoms, leading to the formation of hydrides, chlorides, and oxy acids containing several atoms of sulphur Both sulphur and selenium also present interesting phenomena of allotropy Subjects such as these, as well as the vast range of data that have resulted from the intensive study of compounds such as sulphur dioxide and sulphuric acid, are adequately covered in the new volume On the other hand, it is difficult to discover any reference to the 'parachor', since references to molecular volume and surface tension are not followed by data for this derived function The retention of formulæ which represent sulphur and oxygen as being joined by a non polar double bond follows naturally from this point of view, but is definitely misleading in view of the evidence provided by Sugden and by Phillips that this link is semi polar—a rule to which no exception has yet been found The formulæ thus retained are historically correct, but create a 'pre War' atmosphere, which is not justified by the up-to-date character of the text

Dr Mellor is to be congratulated on the progress which he has made, since he has now covered nearly all the elements except those which occupy the eighth column of Mendeléeff's table These interesting and important elements will, however, probably call for two, if not three, additional volumes, before the task which the author has set himself can be finished Even at this late stage, it may perhaps be useful to suggest that the page headings might be employed to indicate the contents of the sections into which each chapter is divided, instead of repeating the name of the element at the head of each page—for example, more than 300 times in the case of sulphur

Anthropology and Archæology

(1) *The Circle and the Cross a Study in Continuity* By A Hadrian Allcroft In 2 volumes Vol 2 *The Cross* Pp vii + 454 + 4 plates (London Macmillan and Co , Ltd , 1930) 12*s* 6*d* net

(2) *The English Parish Church* By A R Powys (The English Heritage Series) Pp xix + 165 (London, New York and Toronto Longmans, Green and Co , Ltd , 1930) 3*s* 6*d* net

(1) In the first volume of this work, which was published separately, the author made a study of the tradition of the pagan circle In the second, which appears after his death, he has turned to the cross, the early Christian church in Britain and Ireland, and traces its relation to the antecedent circle His thesis is that paganism and Christianity, both being cults of the dead, the converts to the new faith continued to worship at the old holy places, the mounds and burial places of the dead, which became the site of the Christian church, and to use them as the place of interment and of assembly for the discussion of the affairs of the community and for games, feasts, and fairs On a review of the evidence, the author makes out a strong case for carrying this continuity much further in detail than has been done before The identity of the places of worship of Christianity and paganism has been frequently argued , it is supported by the letter of instruction from the Pope to Mellitus permitting the use of pagan shrines for Christian worship, even if other evidence did not point in the same direction Mr Allcroft has greatly extended the field in which continuity of practice and belief must be allowed On certain points, however, he has pressed his theories rather far, as he himself would have been the first to admit His assumption of a widespread Celtic influence in the area of the Saxon church solves many of his problems, but it would be hard to prove

(2) In " The English Parish Church " Mr Powys has given an account of the church as an institution in the rural life of the past, for the benefit of overseas visitors and those of our own public whose interest has been aroused by the efforts now being made to preserve any relics of an earlier day Unlike Mr Allcroft, he holds to the manorial origin of the parish church, and makes the early Saxon church his starting-point His chapter on the secular uses of the church building may profitably be compared with the treatment of the same subject in Mr Allcroft's book

A Book of the Basques By Rodney Gallop Pp xii + 294 + 16 plates (London Macmillan and Co , Ltd , 1930) 15*s* net

Mr Gallop views the Basque with the eye of a realist He heartily condemns imaginative attempts, on insufficient acquaintance, to portray him as a romantic relic of a vanishing race Instead, he finds him a reserved, unimaginative individual, with a strong sense of humour and a pronounced bias towards independence, very markedly shown in his attitude towards his Spanish neighbours in past history While it is true that the Basque is vanishing, it is not the race but the culture that is disappearing A vigorous commercial and industrial activity carries with it development on lines that are purely Spanish It is remarkable that this energy shown by the Basques on the south side of the Pyrenees is not to be found among the French Basques

Mr Gallop does not profess to solve the philological and ethnological problems of the race For the benefit of his readers, he summarises the theories which have been put forward, just as he describes the country and some of the salient events in Basque history, in order to provide a background for and an insight into Basque character His main interest is the primitive culture of the people, and particularly their songs, plays, music, dances, legends and superstitious beliefs All these he describes in considerable detail and analyses with penetrative insight These chapters of Mr Gallop's book will repay detailed examination It is evident that the Basque has a great power of assimilation as well as of improvisation The result is that, while borrowing from outside sources (the origin of some of the folk-music is to be recognised at once as some popular air from another country), the element borrowed has been moulded to conform to a perfectly definite racial type On the other hand, the folk dances present many features of a very primitive character, which Mr Gallop, without doubt rightly, ascribes to a primitive spring ritual

The Bronze Age By Prof V Gordon Childe Pp xii + 258 (Cambridge At the University Press, 1930) 8*s* 6*d* net

Prof Childe's book on the Bronze Age is modest in appearance , but that is no criterion of its merit He has given his readers what might well be termed a complete handbook of the period, having in view the needs of the beginner and that useful person, the general reader He takes up the story of prehistory where it was left by Mr M C Burkitt in " Our Early Ancestors ", and begins with the discovery by early man that certain kinds of stone are susceptible to treatment by heat—the discovery of metal working From this germ he traces the development of Bronze Age culture, highly elaborated in technology and art and relatively advanced in its system of commercial and international communication

The general sketch of cultural conditions is followed by a section on the typology of the Bronze Age, in which the various classes of objects of material culture are passed in review and the development of each within the period is followed up Finally, the history of cultural groups and cultural movements is traced in so far as this may be deduced from the material provided by archæological discovery

It is scarcely necessary to say that Prof Childe's treatment of his subject matter is thorough and individual His unrivalled knowledge of the archæology of the Danubian area enables him to speak with authority on the obscure racial or, as he would prefer to put it, cultural group movements at the beginning of his period He has an interesting if not very conclusive chapter on the races of the Bronze Age, but his most interesting point is his conviction of the persistence of Bronze Age peoples through later periods It is more than probable that he is correct, but he is no less apt in pointing out that in Britain, at any rate, much research is necessary before a definite conclusion can be reached Especially is this true of the bearing of folklore on the question

Decorative Patterns of the Ancient World By Sir Flinders Petrie Pp 17 + 88 plates (London British School of Archæology in Egypt, Bernard Quaritch, Ltd, 1930)

THIS volume is intended to serve as the first outline of an index to "all the decorative imaginings of mankind", an undertaking indeed of no little magnitude Here, however, certain limitations are observed Much sufficiently known already is avoided, the time series limit is set at A D 1000, the examples are drawn only from Europe and western Asia (especially Egypt, Mesopotamia, and the Mediterranean), with their links in other lands Sir Flinders Petrie here touches again on the value of decorative design as presumptive evidence of connexion between the designers, where historic connexion between the designs can be traced, on the ground that purely decorative design has no stimulus of pressure towards use or invention such as that which underlies an essential obviously needed This principle is illustrated often when designs are brought together, as they are here, arranged under their classes Among them, perhaps the most striking example is that with which the series opens, a central figure with an attendant pair of lions, wolves, or other animals, one on either side This is one of the earliest motives of Egypt and Mesopotamia which persists through the ages down to the present day, when it appears as the lion and the unicorn of the Royal Arms and in the supporters of armorial coats

Biology

An Introduction to Vertebrate Embryology By Prof H L Wieman (McGraw-Hill Publications in the Zoölogical Sciences) Pp xi + 411 (New York McGraw Hill Book Co, Inc, London McGraw-Hill Publishing Co, Ltd, 1930) 20*s* net

THERE can be no doubt that the easiest approach to the study of vertebrate anatomy is the development of the embryo and its organogeny In recent years, in American colleges and universities, there has been a tendency to relegate certain of the initial subjects of the crowded medical curriculum to the two pre medical years of study, and to combine the teaching of embryology with comparative anatomy and histology Thus a wider and more generalised field can be covered than is permissible in human embryology alone In the book under review, considerable space has been devoted to questions of general development, cytology, and the early development of *Amphioxus* and the frog Reference is made to some of the more recent work of Spemann, Mangold, and Marx on 'organisms' or embryo-forming materials

As regards the remainder, the treatment of the development of the chick, pig, and man follows conventional lines and draws for its inspiration upon Lillie's "Development of the Chick" and the "Contributions to Embryology" of the Carnegie Institution of Washington Throughout, it has been the aim of the author to direct attention to the experimental aspects of the subject, and to make the descriptive material of the book complement the work in the laboratory, for which a manual has been prepared and published separately

The illustrations are not all that might be desired In the case of those of the development of the human venous system (Figs 161-163) the differentiation of the components is not made sufficiently clear to aid the student in understanding what is a rather complicated series of steps It is doubtful, too, whether the substitution of "sudoriparous" for "sudorific" as applied to the human sweat glands is an improvement in terminology

Histological and Illustrative Methods for Entomologists By Dr H Eltringham With a Chapter on Mounting Whole Insects, by H Britten Pp xi + 139 (Oxford Clarendon Press, London Oxford University Press, 1930) 7*s* 6*d* net

IN the space of 140 pages, Dr Eltringham has been successful in furnishing a concise yet lucid account of the standard methods employed in the study of the anatomy and histology of insects The initial chapters of the book are devoted to a description of the apparatus and materials required for the cutting and staining of sections There is a useful chapter on the dissection and preparation of the genitalia, the characters of which are now extensively used by systematists for the differentiation of species Of not the least importance is the chapter on the mounting of small entire insects, contributed by Mr H Britten, who recommends a method which is at once simple, effective, and time-saving

Every biologist recognises that good illustration is the handmaiden of morphology, and the entomologist with a bias towards anatomy will be encouraged to learn that there are several mechanical aids that can be used in preparing drawings of his subjects that render the lack of a natural artistic ability a matter of minor importance In teaching structural complexities of individual insect parts, models have a decided value, and the author has shown how simple models can be prepared at very little cost Useful hints on the colouring of lantern slides and photographs are also supplied for the benefit of those who are called upon to lecture on entomological topics.

Although it was the admitted intention of the author to cater for the needs of the amateur entomologist with no laboratory training, the book will also prove a useful guide to those who have adopted entomology as a profession A E C

Couleurs et pigments des êtres vivants Par Dr Jean Verne (Collection Armand Colin Section de biologie, No 123) Pp 219 (Paris Armand Colin, 1930) 10 50 francs

At every turn the students of natural history and of biology are compelled to consider the colorations of animals, and the first essential is to know what are the physical and chemical characters of the pigments with which they have to deal—and, if possible, how they are produced Some pigments are excretory, others for respiration, others for nutrition, and others to fix energy (chlorophyll) Living matter has a colour of its own and there are pigments in the blood and other internal tissues, in special pigment cells, usually provided with pseudopodia, and in the exoskeletons of animals Plants have chlorophyll and the colours in fruits are especially interesting Then there are colours due to reflection, to refraction, and to light decomposition Lastly, an animal may be coloured by its food The discussion from the point of view of protective coloration is very short, but it is unnecessary, since the facts relating to all types of colour are given succinctly so that the student may judge for himself We recommend this as a book useful to and within the means of every biologist It has an excellent bibliography

Chemistry

Recent Advances in Physical and Inorganic Chemistry By Prof Alfred W Stewart Sixth edition Pp xi + 387 + 5 plates (London, New York and Toronto Longmans, Green and Co, Ltd, 1930) 18*s* net

The new edition of Prof Stewart's "Recent Advances" provides striking evidence of the rapidity with which fundamental facts and theories of physical and inorganic chemistry have developed, since there is scarcely a single topic in the whole volume which could have been foreseen when the first edition of the book was issued Thus, the foreground of the picture is now occupied by line spectra and X-ray spectra, and the background by band spectra and Tesla-luminescence spectra, whilst the centre is devoted mainly to radioactivity, positive rays, and other aspects of the problem of atomic structure Amongst these chapters on atomic physics, there are interpolated a few of a more chemical character, dealing with newly discovered elements, with various forms of active hydrogen, and with some new hydrides This gives to the book the character of a very modern inorganic chemistry, but the inclusion of physical chemistry in the title is definitely misleading, since there is no reference of any kind to recent advances in this field (as it is commonly defined), with the exception of a belated chapter on "The Donnan Equilibrium", which might have appeared in an earlier edition of the book, but is now wedged uncomfortably between chapters on "The Periodic System" and "Some Flame Reactions"

Whilst, therefore, Prof Stewart has provided an up-to-date report on atomic physics and related topics, it would be a *reductio ad absurdum* to pretend that a book in which dipole moments and strong electrolytes are not mentioned can serve as a guide to the very real advances which have been made in physical chemistry since the War It should, however, be made clear that it is the title of the book that is at fault, and not the contents, since these are full of interest and contain many valuable references to work which is only beginning to find a place in the systematic text-books of inorganic chemistry

The Study of Crystals a General Introduction By T V Barker Pp xvi + 137 (London Thomas Murby and Co, 1930) 8*s* 6*d* net

It is greatly to be hoped that science teachers will respond generously to Dr Barker's efforts to mitigate the ill effects of specialisation in science The subdivision of natural science into several branches, while unavoidable in consequence of the extension of scientific knowledge, is unfortunate The teacher should endeavour to treat science as a unit so far as possible, that his pupils' knowledge may be built on the broadest possible foundations But when it comes to the study of crystalline matter, he is chary of handling a subject he has never been taught Dr Barker's book should assist him greatly, indicating how a study of crystals may readily be incorporated into the usual courses in chemistry and physics Moreover, benefit will be felt in the teaching of solubility and other phase-rule relations, heat and light, and the concept of isomorphism and polymorphism and the like

Of the value of such a course to the pupil, no one can doubt who has met the numerous examples in physical chemistry where the slightest experience in the study of crystals under the microscope would have avoided grave error To those workers who have not had the benefit of such experience or instruction, the book may be cordially recommended, it should help to dispel the illusion that crystallography is essentially and necessarily a matter of difficult trigonometry and of no practical value M H H

A Text-book of Organic Chemistry By Dr A F Holleman Seventh English edition, completely revised with the co-operation of the Author Pp xx + 594 (New York John Wiley and Sons, Inc, London Chapman and Hall, Ltd, 1930) 17*s* 6*d* net

The great success of Prof Holleman's text-book, of which thirty-seven thousand copies have been issued in all and in nine languages, is certainly in part due to the point of view which the author expresses in the preface to the present edition "So long as there is a public to buy it," he says, "a novel can be reprinted unchanged, but even with an interval of only a few years between successive issues, each new edition of a text-book

of chemistry needs not only careful revision, but also the rewriting of some of its chapters" Prof Holleman has taken into account the recent advances in the subject, including the constitution of the dioses, enzymes, and particularly the applications of physical chemistry to organic chemistry—a feature which has always been noteworthy in previous editions More attention is given to fundamentals than in most text books, and in its present form the book is by far the best treatise for students which is available Its use will make the subject interesting and provide a stimulus for further study

The Structure of Silicates By Prof W L Bragg Pp 69 (Leipzig Akademische Verlagsgesellschaft m b H, 1930) 5 gold marks

It is unnecessary to insist on the significance of this monograph from the point of view of the crystallographer Under its somewhat uninviting title it does, however, also include much of interest to the chemist, the points of similarity and dissimilarity between the silicon oxygen complexes which are of such importance in the inorganic world and the carbon chains and rings of organic compounds appearing clearly Other matters of importance which are dealt with are the correct formulæ for silicates—the atomic components should be expressed on the basis of a constant number of oxygen atoms characteristic of the type of structure—and Pauling's ideas upon valence, with the not dissimilar rules for the build of structures which have been developed by W L Bragg and Goldschmidt One feels after reading this book that it was a hopeless task to attempt to unravel crystal structure without the help afforded by X rays, but that now full description of all crystals is likely to be accomplished in the not remote future

Engineering

Johnson's Materials of Construction Rewritten by Prof M O Withey and James Aston Edited by F E Turneaure Seventh edition Pp xxii + 859 (New York John Wiley and Sons, Inc, London Chapman and Hall, Ltd, 1930) 30*s* net

The application of scientific discoveries to engineering practice generally only becomes possible when new technique and new materials have been developed which make possible the application During the last century great advances have been made in engineering, and the success achieved has in no small measure been dependent upon the finding of new materials, developments of accurate methods of testing the properties of materials under ordinary and high temperatures under static and repeated stresses, and how these properties are affected by heat treatments and manufacturing conditions Further, the materials that are used in the largest quantities in modern engineering are irons and steels, which are subject to rapid corrosion in many atmospheric conditions, and thus where possible such metals, as well as the timbers, have to be protected by suitable coverings

The volume before us, after a preliminary study of the mechanics of materials, describes the machines and apparatus required for the carrying out of the many types of tests used in modern engineering practice, and then proceeds to deal with various types of structural materials in detail Timbers, cements, concrete, building stones, structural clays, ferrous and non-ferrous alloys are discussed Constitutional diagrams are given of the copper zinc and copper tin alloys, and interesting chapters are devoted to the effect of heat treatments and the form on the properties of metals Clearly drawn diagrams illustrating these properties, and excellent photomicrographs showing the structure of metals produced by various treatments, are given Chapters are devoted to the preservation of timbers and the corrosion of metals

The book is excellently printed, the diagrams are clear, and the work should prove of great service to engineering students as well as to those in practice

Hydraulics for Engineers and Engineering Students By Prof F C Lea Fifth edition Pp xii + 775 (London Edward Arnold and Co, 1930) 21*s* net

In the course of twenty two years, since its first appearance, Prof Lea's work has passed through five editions, with intermediate reprints—a fact which eloquently speaks for the popularity and acceptability of the volume to students of the subject It has grown considerably in bulk since the present writer reviewed it in Nature in 1908, and now numbers nearly 800 pages Designed to cover the vast field of engineering practice comprised in the modern science of hydraulics, the expansion is scarcely to be wondered at, and, indeed, in turning over the leaves, one does not find that there is any inclusion of inappropriate material or pleonasm of treatment

Nearly a fifth of the volume is devoted to a consideration of turbine and water wheel problems, and another important section of 130 pages is absorbed in a consideration of the subject of centrifugal and reciprocating pumps While the subject as a whole is treated comprehensively and as analytically as one might reasonably expect in a volume which aims at serving the needs of students, it is possible, of course, to point to some matters in which there is room for inclusion of material The treatment of flow in pipes and channels is full, but there is no mention to be found of Dr Herbert Chatley's researches in connexion with the Whangpoo and Yangtse rivers, or more than a meagre reference to the striking conclusions in Barnes' "Hydraulic Flow Reviewed", which the present writer came across on a first perusal, but failed to trace afterwards by means of the index Indeed, the index is a little defective on several points

These, however, are minor details Taking it as a whole, Prof Lea's work is a substantial and serviceable contribution to the literature on hydraulics, and, as heretofore, will be found an extremely useful guide to the practitioner, as well

as to the student The book is admirably produced and the diagrams are clear and distinct

The Elementary Principles of Wireless Telegraphy and Telephony By R D Bangay Third edition revised by O F Brown Pp xii + 268 (London Iliffe and Sons Ltd 1930) 10*s* 6*d* net

To anyone desiring instruction in the principles underlying the working of modern radio apparatus this work can be recommended It is necessary to have a working knowledge of electricity and magnetism and the principles of wave motion This is given first and then we have chapters on aerials receivers masts thermionic valves and triodes their use as amplifiers being explained There is a good chapter on the frequency stabilisation of transmitters descriptions being given both of control by tuning forks and by quartz oscillators The design of a modern broadcast radio receiver is fairly fully described and also the use of a c and d c eliminators

Stress is laid on the danger of amateurs using home made all electric sets which are connected directly with the public electric supply mains There is always a risk that sooner or later one of the outers of the public supply mains may make contact with earth thus raising the potential of the middle main to 200 volts or more In this case there is a real risk from shock and the fire risk is also serious The Institution of Electrical Engineers publishes regulations showing how these risks can be obviated There is a chapter on radio direction finding which gives in little space a description of the Bellini Tosi and the Robinson systems The final chapter discusses the propagation of waves and the causes and effects of atmospherics The lower ionised region of the atmosphere produces little attenuation on very short waves and hence short waves which suffer multiple reflections between the ionised layer and the earth frequently travel better by day than by night No method of eliminating entirely the effects produced by atmospherics has yet been found

Alternating Current Electrical Engineering By W Tolmé Maccall Second edition Pp viii + 496 (London University Tutorial Press Ltd 1930) 15*s*

THIS book can be recommended to students reading for the B Sc examinations of the University of London It gives the necessary groundwork for the electrical technology required in the examination Very little knowledge of the calculus is required and the author s aim has been to make the theoretical part of the subject easily intelligible to the average student This naturally prevents him discussing many of the difficulties that arise He gives however a fair number of references to advanced books and papers We were pleased to notice that he has brought the nomenclature into line with the British Standard Glossary (published by the B E S A) The word capacitance instead of capacity (electrostatic) seems now to be generally adopted

The chapter on harmonic analysis is rather brief No clear distinction is drawn between the Fourier analysis and the Lagrange method of interpolation Perry s method is an example of the former and Runge s method of the latter We think the best and most accurate way of analysing a wave is to apply the modern formulæ for mechanical quadrature to the Fourier integrals It is pointed out that various authors following the interpolation method of Runge have given schedules to facilitate the calculations when the harmonics have to be calculated to the eleventh or beyond One authority quoted divides the half period into 26 ordinates and then gives a schedule for getting the first 25 harmonics inclusive It seems to us that this would be a waste of labour The values of the harmonics above the ninth obtained in this way would probably be inaccurate unless it so happened that no harmonics greater than the twenty fifth were present

Easy Lessons in Television By Robert W Hutchinson Pp vii + 175 (London University Tutorial Press Ltd 1930) 1*s* 9*d*

IT seems fairly certain that television will have a great future but like all inventions it is difficult to predict when it will become commercially successful Of the systems in use that invented by Baird seems to have made the greatest progress and this little book gives an excellent description of it in non technical language Perhaps too much stress is laid in the opening chapter on the atomic nature of electricity It is not very instructive to quote numbers beyond our comprehension A clear description is given of the photoelectric cell which enables a varying light scattered by the object to be televised into a varying current of electricity The varying currents can then be changed by a neon lamp to a fluctuating light which can be received on a screen for television neon is found to be the best gas to use as it responds instantaneously to changes in the current

The thermionic valve and the radio receiving set are described and the book finishes with a description of the televising of a silent film (called telecinematography) television in the theatre and telephotography The Siemens system is used by the Post Office for transmitting pictures to Germany and Denmark the Belin system is largely used in France and the Bell system in the United States

Modern Bridge Construction a Treatise setting forth the Elements of Bridge Design and illustrating Modern Methods of Construction By F Johnstone Taylor Pp xii + 235 (London Crosby Lockwood and Son 1930) 15*s* net

A SHORT treatise on any branch of engineering may serve as an introduction to the subject as a handy book of reference or as a guide to the latest practice The book under notice may well do all these In twelve chapters the author deals in turn with masonry bridges small steel bridges trussed girders girder bridge construction steel bridges constructional details steel arch bridges swing bridges lifting bridges erection methods,

ferro concrete bridges, and suspension bridges The aim of the book in the first place is to meet the needs of the average civil engineer, who requires some knowledge of bridge design, and of the examination candidate It covers the ground in a plain, straightforward manner The use of higher mathematics has been avoided so far as possible, the diagrams are clear, and there are numerous references to recent bridge construction as described in the *Engineer*, *Engineering*, and other journals

Geography

Cornwall a Survey of its Coast, Moors and Valleys, with Suggestions for the Preservation of Amenities Prepared by W Harding Thompson for the Cornwall Branch of the Council for the Preservation of Rural England With Notes on the Antiquities of Cornwall, by Charles Henderson Pp xix + 130 + 42 plates (London University of London Press, Ltd , 1930) 17*s* 6*d* net

ANOTHER handsome, well illustrated quarto has been added to the library dealing with the preservation of English landscape The suggestions of most general importance are those relating to the coast Support is given (so far as concerns Cornwall) to the proposals which have been made to the National Park Committee, that in Cornwall and the opposite peninsula of Pembrokeshire the National Coast Parks of Britain should be situate In the opinion of the authors of the Cornwall survey, " The formation of a National Coastal Park would afford lasting benefit to visitors from urban centres, and incidentally it would benefit a county suffering from acute industrial depression

The frontages for coastal parks, shown in a special map, are nearly the same as those suggested in my evidence to the National Park Committee and my book upon the subject , but the authors of the present survey have improved upon those suggestions in one important particular, namely, by extending farther inland the proposed coast park on the west of St Ives, so as to include the district of prehistoric monuments which here, as in the Pembrokeshire promontories add greatly to the romantic interest of the scene The recommendation also that steps should be taken " with a view to keeping open a public footpath all round the coasts of Cornwall " is welcome This is, indeed, a matter which should engage the immediate attention of local authorities in every maritime county

VAUGHAN CORNISH

Grundzüge der Physiogeographie Mit Benutzung von W M Davis *Physical Geography* und der deutschen Ausgaben , zum Gebrauch beim Studium und auf Exkursionen Neu bearbeitet von Prof Dr Gustav Braun Band 1 *Spezielle Physiogeographie* Pp xii + 178 8 gold marks Band 2 *Allgemeine vergleichende Physiogeographie* Dritte Auflage Pp xii + 256 10 gold marks (Leipzig und Berlin B G Teubner, 1930)

PROF BRAUN has based this small text book of physical geography on the well known volume of Prof W M Davis which first appeared in 1889 and afterwards was translated into German The work has undergone thorough revision, which entailed rewriting several of the sections, including those on weather and climate It covers the whole groundwork of the subject, including the distribution of vegetation Some of the original illustrations remain, but many are new or derived from various sources, and their excellence is one of the best features of the book Particular attention has been paid to reference to original sources and each section has copious reference to books and papers A glossary of English and German technical terms is a useful addition The book should prove of great value to students, and fully equals any work of the same standard now available in English

Death Valley the Facts By W A Chalfant Pp ix + 155 + 16 plates (Stanford University, Calif Stanford University Press , London Oxford University Press, 1930) 16*s* net

Grand Canyon Country By M R Tillotson and Frank J Taylor Pp viii + 108 + 15 plates (Stanford University, Calif Stanford University Press , London Oxford University Press, 1929) 9*s* net

THESE two small and beautifully produced volumes, although they bear no indication of belonging to any series, have considerable resemblance in their point of view and scope Neither deals with new material nor is in the nature of a personal narrative, but both give useful summaries of facts of history and physical conditions They are, in short, handbooks of scientific information The volume on the Death Valley is the fullest and contains useful chapters on plant and animal life, in addition to sections on physical geography and geology Each volume has some well chosen photographic illustrations and a 'cartograph' or pictorial map printed on the end papers That of the Grand Canyon country is so full of whimsical pictures scattered over the map that a popular use of the volume is suggested The Death Valley map has no flights in imagination

Geology

Geochemie in ausgewählten Kapiteln Von W J Vernadsky Autorisierte Übersetzung aus dem Russischen von Dr E Kordes Pp xii + 370 (Leipzig Akademische Verlagsgesellschaft m b H , 1930) 25 gold marks

CLARKE'S invaluable " Data of Geochemistry " is justly so highly esteemed, especially in English speaking countries, that there has been a natural tendency to regard it not only as an indispensable compilation of data but also as a standard exposition of geochemistry itself Only recently has this tendency been checked by growing acquaintance with the brilliant work of Fersman, Vernadsky, and Goldschmidt A most useful and illuminating little book was published in French by Vernadsky in 1924 under the title " La Géochimie " In 1927 a revised translation appeared in Russian, and now a third and greatly enlarged

edition has become available, this time in German After an historical introduction, the mode of occurrence of the chemical elements in the earth's crust is passed in review, with special reference to their concentrated or dispersed distribution in the successive earth shells, including that of the biosphere The succeeding chapters deal in great detail with the geochemistry of manganese with silicon and silicate minerals, including the parts played by compounds of aluminium and iron and the significance of the colloidal state, with the carbon cycle and the geochemical activities of living organisms, and finally with the distribution of the radioactive elements and their relation to lead and helium and the earth's thermal history The book concludes with an excellent annotated bibliography and indexes of authors and subjects

The author is to be congratulated on a work of fascinating interest, imbued throughout with the spirit of research, and touching everywhere on points of great importance to geology and chemistry that are generally passed over in more formal text books As three other languages have already had their turn, we may perhaps be allowed to express the hope that when the fourth edition is prepared it may be published in English Its welcome is already assured

American Mesozoic Mammalia By George Gaylord Simpson (*Memoirs of the Peabody Museum of Yale University*, Vol 3, Part 1) (Published on the Othniel Charles Marsh Publication Fund) Pp xv + 235 (32 plates) (New Haven Yale University Press, London Oxford University Press, 1929) 5 dollars

This work forms a companion volume to the same author's monograph on the European Mesozoic mammals which was published in 1928 as a catalogue by the Trustees of the British Museum In the present volume the author has rounded off his investigations by a description of the pre Tertiary mammals of the American continent While there are here no faunas at present known quite so early as the Rhætic and Middle Jurassic of the Old World, there are, on the other hand, at least a few places where Cretaceous mammal remains occur A knowledge of what happened in this period is so essential to our understanding of the evolution of placental and marsupial lines, and the localities and their yield of specimens so scarce that the dozen genera of marsupials and three of placentals here catalogued by Dr Simpson acquire considerable importance

A large part of the general description of the six Mesozoic orders of mammals has already been given in the British Museum Catalogue, where also questions as to their reptilian origin and their interrelationships are fully discussed To this every reader of the present memoir will have to refer The two works with their excellent plates and figures, and the sound and workmanlike treatment of the subject, form an admirable and useful treatise

Limestones their Origins, Distribution and Uses By Dr F J North Pp xxiii + 467 (London Thomas Murby and Co, New York D Van Nostrand Co, 1930) 16s net

Few people realise the importance of the part played by limestone in the economic life of the nation It enters into nearly every phase of human industry, and on its varied uses Dr North has written a most interesting and readable book No aspect of the subject appears to have escaped his attention, he deals with the origin of limestones and their distribution in the various geological formations in such a manner as to make the book an excellent introduction to the science of geology, and it may be recommended confidently to the general reader who desires to know something of the history of the earth The book is profusely illustrated, and to each chapter is appended a list of references which form a useful bibliography of the subject

As evidence of the care taken by the author, the book is remarkably free from errors One, however, may be pointed out On page 242 it is stated that the lower part of the Speeton Clay "is of Jurassic age (corresponding to Portland and Purbeck Beds)" A similar mistake is to be found on page 185 There are no marine representatives of the Portland and Purbeck rocks in Yorkshire the beds referred to by Dr North are now placed in the Lower Cretaceous

Mathematics

Theory of Functionals and of Integral and Integro-Differential Equations By Prof Vito Volterra Edited by Prof Luigi Fantappiè Authorised translation by Miss M Long Pp xiv + 226 (London, Glasgow and Bombay Blackie and Son, Ltd, 1930) 25s net

This translation of lectures, delivered in 1925 before the University of Madrid and since corrected and improved by the author, gives a concise survey of 'functionals', first studied by him in 1887 under the name of "functions depending on other functions", and later called "functions of lines" The first chapter gives definitions, properties of functionals, and operations performed on them The second chapter treats of problems of the functional calculus and in particular of integral equations Then follows a chapter on the extension of the concept 'analytic function' to functionals and, more particularly, extensions of the Riemann and Cauchy theories of conjugate functions in the xy plane to conjugate functions in space The fourth chapter treats of the composition and permutability of functions, and leads to an extension of the concept 'power series of a variable' to functionals The fifth chapter deals with integro-differential equations and functional derivative equations and their relations to the Hamilton-Jacobi theory, the new quantum electro-dynamics, and Green's functions The last chapter gives a summary of the applications of functionals to a variety of topics, in order to give some idea of the wide range of the subject matter of the lectures we

may mention the calculus of variations, oscillations of lakes and membranes, and hereditary problems in dynamics, elasticity, and electromagnetism

As the treatment is very concise, and detailed proofs are rare, the book is difficult to read, but full bibliographies appended to the various chapters, frequent references in the text, and an excellent translation will no doubt prove of great assistance to the reader No one interested in the topics dealt with can afford to ignore this work by one of the most prominent Italian mathematicians

Vectorial Mechanics By Prof Louis Brand Pp xvii + 544 (New York John Wiley and Sons, Inc , London Chapman and Hall, Ltd , 1930) 25s net

THE book before us is intended as " an introductory text book on mechanics for students of engineering and physics " It fulfils the first of these functions perfectly, in so far as it includes a great number of problems and worked examples chosen from topics of special interest to engineers Physicists, how ever, are not so well catered for, and unfortunately some of the fundamental principles are not given in a form sufficiently general for the purposes of modern physics Thus, Newton's Second Law is stated only for invariable masses, and the Third Law only for central forces, no provision being made for extensions to relativity problems and to electromagnetic systems

These are but slight blemishes on an otherwise excellent book which should prove of great use to engineering students Vector methods are used freely and are sufficiently explained in two chapters on vector algebra and vector calculus A chapter is devoted to three dimensional statics, and it includes an elegant method of reducing the general system of forces, first to two forces and then to a force and couple There is a long chapter on the kinematics of plane motion with applications to linkages and various gears, and another on the dynamics of rigid bodies with applications to the balancing of masses, to governors of various types, and to the gyroscope as used in engineering Although intended primarily for students in American universities, it will no doubt be of interest also to English students and teachers

Topology By Prof Solomon Lefschetz (American Mathematical Society Colloquium Publications, Vol 12) Pp ix + 410 (New York American Mathematical Society , Berlin Hirschwaldsche Buchhandlung , Cambridge Bowes and Bowes, 1930) 4 50 dollars

THE monograph under review illustrates in a striking way the great progress made in mathematics in recent years even in so specialised a branch as *Analysis Situs*, for the bibliography includes nearly three hundred references, almost all to papers published during the last decade The work is not a text-book, but, as it were, a digest of research work done in the subject since the publication of Veblen's " Analysis Situs " in 1922 Consequently, it makes great demands on the reader's knowledge, and is not suitable as an introduction to the subject , but it is of great importance to the expert in topology, and will prove to be a mine of information for all engaged in research in this field

The topics treated are the elementary combinatorial theory of complexes, the topological invariance of the homology characters, manifolds and their duality theorems, chains on a manifold, product complexes, transformation of manifolds and infinite complexes, with applications to analysis and algebraic geometry The book is well arranged and clearly written, as may be expected from one who, like the author, has distinguished himself by research in the subject, and appears likely to exert a beneficial influence on future research

Miscellany

George Eastman By Carl W Ackerman Pp xviii + 522 + 25 plates (London Constable and Co , Ltd , 1930) 24s net

GEORGE EASTMAN is a man of great faith, enormous energy, and indomitable perseverance He left school at fourteen years of age (1868) and worked in an assurance agency, and a year later he became practically interested in photography In 1877, after he had been working hard making emulsions and a coating machine, often all night, for he was still engaged as a clerk during the day, he determined to make plates commercially, and in 1879 he patented his coating machine, and in 1880 he was in business for himself In 1884 he got the notion of a transparent film, and was obsessed with its advantages , and in the same year, in conjunction with Mr Walker, he patented the roll holder These were the beginnings of the Eastman Kodak Company

The company has not always sailed in smooth waters—far from it, but when his partners were pessimistic, when some of his employees conspired against him, when the Government took action against him because of the vastness of his business, and when in early times the company was in debt, Mr Eastman was always optimistic He wrote "The manifest destiny of the Eastman Kodak Company is to be the largest manufacturer of photographic materials in the world, or else to go to pot ", and he took good care to realise the former alternative He also wrote " I am a believer in one man management and that a Board of Directors is valuable only as an advisory instrument to a good manager " He believed in full-page advertisements and many of them In the year 1896 he made his one hundred thousandth kodak, and at the factories at Rochester (N Y) and Harrow was making about one hundred miles a week of film and photographic paper Mr Eastman has been a great and generally anonymous helper of the needy all his life, increasing his gifts as he was able until they reached millions of dollars

The author has used the enormous mass of documents at his disposal with much skill in writing the fourteen chapters, or essays, of which the book consists, and has appended a very full and useful index

The Indexing of Books and Periodicals By Dr John W T Walsh Pp 118 (London Edward Arnold and Co, 1930) 6s net

It cannot yet be said that the good index is the general rule, whether for books or for periodical literature, and no reader of NATURE will regard a new book on the subject as superfluous Dr Walsh's book does not deal with main theorétical principles, and contains little that is new for actual practice, but the main features that make for good indexing cannot be repeated too often, and they are here, on the whole, set out with due emphasis

Dr Walsh is, however, not always clear in his directions For example, an alphabetical series such as "Cat, Domestic—Catfish—Catgut—Cat skins" is characterised as most undesirable on one page, but appears to be justified by the rule given on the next And why does Dr Walsh say that the most suitable form of index for 'abstract' journals is the classified form, with a reference to the Brussels decimal scheme? It is not easy to see why this type of journal should be placed for this purpose in a class by itself, and why the alphabetical arrangement should here be discarded It may be advisable for the abstracts themselves to be arranged in class order, for they are designed to be used at the moment of publication as a survey of the current literature of their subject But for the annual index, which is only as a rule a finding tool for some specific feature and ought not to take the place of a 'contents list' (as Dr Walsh rightly points out), the arrangement would be most inconvenient In any case the inclusion of the suggestion without elaboration will only confuse the class of reader for whom this book is designed

The author has evidently read widely on his subject, but seems to have been unduly influenced by works on general cataloguing and classification, which have to some extent obscured for him the real nature and function of the index For all that, the book is a practical manual which contains much that will help the inexperienced

God in Christian Thought and Experience By the Rev W R Matthews (Library of Constructive Theology) Pp xix + 283 (London Nisbet and Co, Ltd, 1930) 10s 6d net

"To a discerning eye", says Dr Matthews in his preface, "it must be clear that the main question which is being decided in the world to-day, is whether or not the majority of men shall continue to believe in God" One of the difficulties with which the would-be constructor of a tenable theistic theory is faced is the absence of any generally accepted philosophy All we can boast is "a generally accepted body of knowledge which stands for the modern world as solid and unquestionable as the logic and metaphysic of Aristotle stood for the later Middle Ages", that is to say, natural science Yet science does not seem able to provide us with any solution of ultimate problems Here it leaves us unsatisfied

There is scope, then, for someone who, starting from the commonly accepted results of natural science, will tell us as much as he can from that point of view, and indicate exactly what we must *not* hope to learn from him Dr Matthews does not claim to attack the problem from this end, he takes as his starting point "the Christian experience of God", and tries, in view of it, to formulate a theory of the divine nature which may be acceptable to the reason, and not contradictory to the knowledge, of modern men Thus his book will interest theologians more than men of science Yet scientific workers may well acclaim any work which will enlighten theologians, and this the present volume can scarcely fail to do

Philosophy and Psychology

(1) *The Psychology of Insanity* By Dr Bernard Hart (The Cambridge Manuals of Science and Literature) Fourth edition Pp xxxv + 176 (Cambridge At the University Press, 1930) 3s net

(2) *Psychopathology its Development and its Place in Medicine* By Dr Bernard Hart Second edition Pp vii + 178 (Cambridge At the University Press, 1929) 8s 6d net

(1) DR BERNARD HART's little book has been reprinted almost annually since 1918, and now we have a new edition, the fourth The book gives an extraordinarily good account of insanity and may well be read by any educated layman, particularly the social worker, with great benefit Hart explains mental mechanisms like projections, which are of such common occurrence in the everyday life of the normal 'man in the street' This edition has had an introduction specially written for it, in which Hart gives a brief historical account of the influence of Janet but more particularly of Freud He points out how Freud's views have been developed and extended, although the original ideas remain much the same We cannot help thinking that everyone ought to read this book, and that the mental hygiene of the community would benefit by it

(2) In "Psychopathology" Dr Bernard Hart presents us with his Goulstonian Lectures delivered in 1926, with the addition of three chapters one on the psychology of rumour, one on the methods of psychotherapy, and one on the conception of dissociation These last three papers had all been published already Dr Hart naturally devotes a large amount of his space to the views of Freud He also amply considers the views of Jung, but unfortunately appears to have little use for the theories of Adler These, we think, might have been given more space, as they appeal to quite a number of clinicians who do not accept Freud's all-embracing use of the word sex

Lectures on Ethics By Immanuel Kant Translated from the German by Louis Infield Pp xiv + 253 (London Methuen and Co, Ltd, 1930) 10s 6d net

It is much to be hoped that this little book will attain a wide circulation It has several points of special interest, besides being a short handbook of practical morals, easily and pointedly written and with clear anticipation of the great thinker's main construction of ethics, which followed shortly after-

wards, in 1781 The interesting literary point is that we have in this book, taken down very fully or written out immediately afterwards, Kant's own words in lecturing, and the result is very similar, from the literary point of view, to most of the works of Aristotle

The main note of Kant's moral system is struck in the earlier section, where he puts aside the Aristotelian doctrine of the mean as an obvious idea of no depth or scope, and lays down his own canon of the moral imperative

Two other points of special interest to contemporary thought stand out conspicuously One is the frequent reference to the claim of mankind as a whole "We should have but a low opinion of ourselves as individuals, but as representatives of mankind we ought to hold ourselves in high esteem" We are to do right not because it is the will of God, though we are led also to believe that it is that, but because it is the prerogative of our nature to do so, all mankind speaking to us through the individual conscience

The other salient point is the ideal agreement of mankind, which gives us in its purest form the sanction of the moral imperative, and should, in the practical and political form, be the object of all good men to achieve by law and institution on earth Kant's defence and advocacy of a League of Nations is nowhere more convincingly and fervently expressed than in the concluding paragraphs, which might well be adopted as a motto by the League of to-day F S M

The Human Mind By Karl A Menninger Pp xiv + 477 + xi (New York and London Alfred A Knopf, 1930) 21*s*

Dr Menninger, who is a well-known American psychiatrist, has attempted to place before the lay reader the problems of mental disorder This is a difficult task, for the subject is a highly technical one, and to make it intelligible and at the same time preserve its dignity would appear to be a task of the severest Yet the author has presented what is probably the best account of the human mind viewed from the abnormal side It is a book which may be read to great advantage by psychiatrists as well as the lay reader The author's explanation of mental mechanisms looked at from an analytic point of view is excellent, and his case records, which are perhaps the most fascinating part of the book, show an extraordinarily wide and sympathetic understanding of the distraught mind Some of the explanations of aberrant conduct may appear exaggerated to the uninitiated, but they are very familiar to those who have to deal with the mentally abnormal

Don Juan and other Psychological Studies By Prof Gonzalo R Lafora Translated by Janet H Perry Pp 288 (London Thornton Butterworth, Ltd , 1930) 7*s* 6*d* net

In "Don Juan and other Psychological Studies", Prof. Lafora, who occupies the chair in psychiatry of the University of Madrid, presents us with a series of most interesting studies of the abnormal He describes a patient of his own who very closely resembles the personality of Don Juan, and considers that it was quite possible for an individual so hopelessly erotic as Don Juan to have existed In his chapter on lay and religious miraculous cures, he points out that in Lourdes in 1923 only eighteen out of nearly a million invalids who attended were cured At the same time, no figures are provided of the many who die or are worn out by the journey A certain number of the cures relapse, yet we are told nothing of this In his study of cubism and expressionism he points out, as others have done, the resemblance between this form of art and the drawings of so many of the insane It is quite impossible to tell from a given picture whether the artist was sane or insane With this statement of the author's we are heartily in agreement The book throughout is a most level headed exposition of the abnormal, and to anyone familiar with the writings and drawings of the insane and mentally unbalanced it will appear by no means as an exaggeration

Sleep Why we need It, and How to get It By Dr Donald A Laird and Charles G Muller Pp x + 212 (London Williams and Norgate, Ltd , 1930) 6*s* net

Laird and Muller have made an excellent attempt to solve some of the problems of sleep in a practical manner It is typically American One is inclined to take the statement that 60° F is too cold for children to do good work *cum grano salis* The book, however, is full of practical points, such as small hints for diminishing noise, etc It is doubtful if in Great Britain many people lie and read in bed with a lamp attached to the book they are reading so as to assure a constant volume of light We cannot imagine moth balls helping to woo sleep Coffee is found to be not guilty of very many of the cases of disturbance of sleep laid at its door Excitement during the evening is a much more important sinner

Physics

A Treatise on Light By Dr R A Houstoun Sixth edition Pp xi + 494 (London, New York and Toronto Longmans, Green and Co , Ltd , 1930) 12*s* 6*d* net

This treatise, which is now in its sixth edition, is an admirably well balanced book It is divided into four parts The first treats of geometrical optics, a subject which some physicists forget is of great practical value The second discusses physical optics, finishing with the Kerr effect In part three, spectroscopy and photometry are discussed and the latest developments are described We expected the author to be more definite about colour blindness, on which he is an authority, but he has, perhaps wisely, confined himself to a brief statement of the main theories The descriptions given of the wonderful advances made in spectroscopy the spectral series, the infra-red, the ultra-violet, and the X-rays will be helpful to many The last section of the book gives the foundations of the mathematical theory and its later developments, due stress being laid on the quantum theories of the propagation of light and on Poynting's theory

of the pressure of light The chapter on ether and relativity is interesting The usual unconvincing statements are made about the relativity of time and space The author says, " Relativity is consequently now accepted as a faith It is inadvisable to devote attention to its paradoxical aspects ' The warning perhaps means that ' this way madness lies ', and many will agree with him It is pointed out that if we adopt Einstein's theory, since every observer has his own system of space and time, it is easier to abandon the conception of an ether and think of the light itself as having substance and moving through the void A description of the Hilger interferometer, Moseley's work on X ray spectra, cosmic radiation, and Kodacolor photography completes this useful volume

The Physics of Solids and Fluids with Recent Developments By P P Ewald, Th Pöschl, and L Prandtl Authorised translation by Dr J Dougall and W M Deans Pp xii + 372 + 4 plates (London, Glasgow and Bombay Blackie and Son, Ltd , 1930) 17s 6d net

ALTHOUGH of recent years the attention of physicists has been so much concentrated on electrons and quanta, the study of the properties of matter in the solid and liquid states has made great progress, with the result that text books on the subject have been growing old fashioned This volume contains a number of articles which appeared as part of the eleventh edition of Muller Pouillet's ' Lehrbuch der Physik ", and it is satisfactory to have them translated into English and collected in this convenient form Prof Poschl, of Karlsruhe, contributes an interesting chapter on elasticity and strength of materials, and a short chapter on the friction of solid bodies Prof Ewald writes a chapter on the mechanical structure of solids from the atomic point of view, in which the lattice theory of crystals is described and a useful account of single crystals is given Finally, Prof Prandtl, of Gottingen, contributes three chapters on the equilibrium and the flow of liquids and gases These are to be recommended to anyone taking up the scientific study of aerodynamics The illustrations are noteworthy, and special mention must be made of the fine photographs of slip and fracture by Dr G Sachs and those of stream lines in air and in water

Einführung in die Theorie der Wärme zum Gebrauch bei Vortragen, sowie zum Selbstunterricht Von Prof Dr Max Planck (*Einführung in die theoretische Physik*, von Prof Dr Max Planck, Band 5) Pp vii + 251 (Leipzig S Hirzel, 1930) 8 gold marks

THIS book is the last volume of a series entitled ' An Introduction to Theoretical Physics ", and it is in keeping with Planck's work that the last volume is on the theory of heat instead of the theory of electricity and magnetism Planck has shown that the theory of heat can be built upon the foundation of mechanics and electromagnetism

It is not intended that this volume should replace the two works on thermodynamics and heat radiation, so well known to all students of physics These branches of the study of heat are treated here in less detail, and an introduction to the theory of heat must have a more general character It is in four parts, and the content of the first, third, and fourth is familiar to students of Planck s contributions to the theory of heat These make very pleasant reading, especially the first part, for it is always a delight to read Planck on the laws of thermodynamics The second part is on the conduction of heat, and is the only part which tends to relieve the work of its rather specialised character It is an introduction to certain parts of the subject of heat rather than to the general theory

Les quanta Par Prof Georges Déjardin (Collection Armand Colin Section de physique, No 121) Pp 224 (Paris Armand Colin, 1930) 10 50 francs

PROF DEJARDIN'S ' modeste ouvrage " is actually an exceptionally good account of quantum theory in which he shows a nice appreciation of the extent to which mathematics can be tolerated by the ordinary honours student of physics The course followed is the historical one, the radiation problem being taken first, and, after that, specific heats, the photoelectric effect, the scattering of X rays, elementary spectroscopic theory, and, finally, the new quantum mechanics Details of experiments are not given, but there is no lack of illustrative results, generally from fairly recent publications There is a great deal to be said for the omission of such details even from more pretentious treatises, the student being left to refer to original papers for these—with of course precise directions as to what he is to read Prof Déjardin has succeeded in covering much ground in this small and inexpensive volume which if read in conjunction with P Bricout s Ondes et electrons , in the same series, furnishes a very satisfactory course on modern physics

Theoretical Mechanics the Theory of the Potential By Prof William Duncan MacMillan Pp xiii + 469 (New York McGraw Hill Book Co , Inc , London McGraw Hill Publishing Co , Ltd , 1930) 25s net

To the author's remark that the theory of the potential is very useful from the point of view of the physicist and very beautiful from the point of view of the mathematician, we may add that it introduces a class of functions of fundamental importance in connexion with wave mechanics Whether they are best approached for this purpose in the way given by Prof Macmillan is perhaps questionable, but there is no doubt that anyone who had worked through this volume would be quite familiar with many of their properties The ground covered is much the same as in several of the larger treatises on electricity, but the subject is here approached with a minimum of specific reference to the nature of the field A knowledge of the theory of integral equations is not assumed The one criticism offered is that rather much space has been devoted in the early chapters to the solution of distinctly elementary problems

Forthcoming Books of Science.

Printed in Great Britain by R. & R. CLARK, LIMITED, *Edinburgh*

a Camera" Mr Maxwell visited the Birunga mountains in the spring of 1925 to study the habits and habitat of the eastern gorilla The series includes a photograph of a female gorilla startled by the photographer and making off in the foreground, carrying her young one on her back, and one showing the head and shoulders of an old male gorilla peering out from a dense curtain of tropical vegetation There is also a series of photographs of gorilla beds, or nests', one is constructed in the fork of a tree about 4 feet from the ground, but the older gorillas appear to prefer their beds on the ground itself, probably because they have little fear of leopards The Trustees have agreed to the purchase of a valuable collection of West African birds made by Mr G L Bates, principally in the highlands of the north eastern part of Sierra Leone and the adjacent French territory On the isolated peaks culminating in Mount Nimba were procured stonechats and pipits, the nearest relations of which are in the Cameroon highlands, hundreds of miles to the south Two specimens and photographs of the 'Coco de Mer' (*Lodoicea Sechellarum* Labill) have been presented to the Department of Botany by Miss Royston of Clophill, Bedfordshire The fruits are those of a palm which is restricted to the Seychelles, and were found floating in the Indian Ocean long before the tree itself was known The fruit is one of the largest known, the weight of one of those presented, though the specimen is hollow, is 30 lb A collection of some 2600 letters, many containing valuable mycological data, addressed to William Phillips, have been presented by Mr J Ramsbottom Phillips was a well known mycologist of the latter part of the last century, and wrote the Manual of the British Discomycetes"

Prof S Hanzlik has published a useful preliminary report on the unification of rainfall recording in *Bulletin* No 5 of Section d'Hydrologie, Union Géodésique et Géophysique Internationale, Venice, 1927 Numerous kinds of rain gauges are used in different countries, with reception areas ranging from 64 to 1000 square centimetres There is equally great variation in the height of the sides of the rain gauge and in other features Various practices obtain in the measure of snowfall Self registering rain gauges differ widely in principle The amount of rainfall in some countries is recorded on the day it falls in others on the day it is measured, which is the day following its fall Generally a "rainy day" is one on which at least 0 01 mm of rain fell, but in some countries 0 02 or even 0 5 mm is the minimum In some statistics the days with certain quantities of rain are distinguished, in others different quantities are chosen There are also various practices in the recording of frost and other phenomena The report is based on inquiries addressed to seventy eight meteorological institutes throughout the world It is not exhaustive, but yet is of much interest, and if it does nothing to suggest uniformity, it shows at least the wide diversity of methods employed in various countries Without some measure of uniformity, the comparison and discussion of meteorological data are made unnecessarily difficult

The Ordnance Survey has published a map of seventeenth century England and Wales as the second of the series of period maps of which Roman Britain was the first The basis of this map is a layer coloured, contoured sheet on a scale of one to a million The main roads are taken from Ogilby's survey of 1672 The principal ports and towns are shown by different symbols which indicate their importance Other symbols are used for castles, large houses, forts, and camp sites The chief events of the Civil War, with their dates, are indicated In many parts of the country the principal economic products are marked Forests are indicated by names but not symbols In spite of the large amount of information given, the map is clear and legible and gives no impression of crowding It is both a useful document and a fine specimen of cartographical skill A small plan of contemporary London is bound up with the map Prof G M Trevelyan contributes a short introduction on the general appearance of England in that century, and Dr J E Morris gives an outline of the campaigns of the Civil War There are also lists of events and prominent persons of the century Full details of the sources of the map are given The map alone is published on paper at two and sixpence, or mounted on linen with letterpress at six shillings The plan of London can be obtained separately at one shilling

The Reports on the health of the Navy and of the Army for the year 1929 have recently been issued (London H M Stationery Office Price 2s 6d and 3s net, respectively) In the Navy, the ratio of the incidence of disease was 482 03 per 1000 of the strength, being an increase of 36 04 over 1928 and of 14 91 in comparison with the five years' average There was some increase in venereal diseases, with 6361 cases, and in malaria, and a number of cases of influenza occurred On the other hand, there were only three cases of typhoid fever and two of paratyphoid fever, a remarkable record in a force of 86,240 men The total number of deaths was 254, of which 101 were due to injury In the Army, likewise, there has been some increase in the incidence of disease, the admission ratio having risen from 426 2 in 1928 to 468 5 in 1929 per 1000 of the strength This increase was, however, mainly due to an epidemic of influenza in the home commands, during the early months of the year Several diseases show a slight increase in the admission ratio compared with 1928, and the death and invaliding ratios also show slight increases Tonsilitis, which has been increasingly prevalent during recent years, again shows an increase. There were more cases of malaria in India, and one case of this disease arising in England is mentioned The patient had never been to a malarious country, and had been for more than ten years continuously in Great Britain The malaria parasite was found in his blood, so that there is no question of the diagnosis Venereal diseases show a satisfactory decrease

Fossil shells of ostrich eggs were found by the 1923 expedition of the American Museum of Natural History in the Central Gobi, and now A Tugarinov

(*Priroda*, 1930, No 7 8) reports the discovery of fragments of such shells in a number of localities around Troitzkosavsk, in Transbaikalia, which means a considerable northward extension of the area where ostriches occurred Most of the finds were made in an association with various objects of palæolithic culture, but in one case, fragments of shells were found away from any traces of human habitation The association of the shells with palæolithic camps and the fact that some fragments are perforated indicate that they were used as a material for making utensils As may be concluded from the size and the structure of the shells, they belonged to a species closely allied to *Struthio camelus*, the living North African ostrich, which differs strongly in these respects from the more southern species However, it does not appear possible to identify the Transbaikalian species with the North African one This discovery forms an interesting counterpart to the fact that the environs of Troitzkosavsk harbour fossil remains of an antelope of the genus *Spirocerus*, also allied to some recent African genera

RECENTLY we referred in these notes to the many problems of bird life in Britain which still await solution Yet birds are the creatures most observed by the amateur naturalist It need scarcely be said, therefore, that our knowledge of the habits, life histories, and reactions of mammals has many blanks, in spite of the fact that few branches of inquiry are of greater interest to the naturalist or of more practical importance to the agriculturist Moreover, it is just along the lines of observation most open to the field naturalist, such as the relationships of animals to their environment or the fluctuations of their numbers seasonally and annually, that further information is needed An excellent guide for the worker who desires to make useful contributions to such knowledge is Walter P Taylor's "Outlines for Studies of Mammalian Life Histories", a 12 page pamphlet recently issued in revised form by the U S Department of Agriculture (*Miscell Pub*, No 86, 1930) In the comprehensive scheme of studies outlined there, the author indicates the observations which ought to be made in elucidating the environment and its influence, the life history, structure and behaviour, and the relationship between the lower mammals and man The suggestions should stimulate systematised observations in the field

WE have received a letter from Col L A Waddell in which he takes exception to our notice of his book, "Egyptian Civilization its Sumerian Origin", in NATURE of Jan 24 He states that the fact is overlooked that it gives the fully attested inscriptional evidence for the complete identity of the pre-dynastic and dynastic Pharaohs with Sumerian emperors and their dynasties in Mesopotamia, based on the exact agreement which has been worked out for their names, achievements and order of succession He adds that so far from his chronology "hanging in the air", he has provided a solid foundation of fact for the first time for a chronology of Egypt, whereas those who follow what our notice termed the "orthodox" system differ among themselves by some thousands of years in the dates of the early dynasties While we have pleasure in placing Col Waddell's protest on record, it is evident that it restates, in brief, the argument of his book, which is dependent upon identifications which, it was made clear, we were not prepared to accept

GREAT progress has been made in the United States of America in the formation of children's museums In discussing "Children's Museums in our National Life", at Yale University on Nov 19, Miss Anna B Gallup pointed out that such institutions are now flourishing in Detroit, Indianapolis, Boston, Hartford, and Los Angeles, besides the children's museums maintained by Harvard and Yale Universities In addition to these seven, all established after the organisation of the original example at Brooklyn, others are on the way In Kansas City a small museum for children is soon to be opened, another is being planned as part of the California Academy of Sciences, and in Pasadena the movement has taken hold Even in Honolulu a building has been under consideration for the use of children, and a representative has studied the methods of the Brooklyn Children's Museum in order that the most may be made of the educational possibilities of the venture

THE *Bulletin* of the Michigan College of Mining and Technology for the year 1930–1931, which has recently been issued, contains full schedules of the subjects taught at this seat of learning Judging by the scope of the work detailed for chemistry, engineering, mining, metallurgy, etc, and from the illustrations scattered through the book, a very thorough education is made possible by the possession of first class equipment housed in ideal buildings and handled by a very competent staff That is where these schools of advanced instruction in the United States score over so many British centres of learning of similar standing, lack of adequate equipment or accommodation is bemoaned in almost every university in Great Britain in some faculty or other, but it is seldom that the same cry is heard from the other side To those interested in schemes of work and curricula, in questions of relative number of hours per subject in a group chosen for a degree course, it is instructive to turn to publications which tell us how other people do things, how qualifications are secured While headings and schedules can give little idea of the quality of the teaching or of the standard really achieved short of or compatible with the aims professed, much can be learned from perusal of a pamphlet of this kind, and correct assessment of international educational values is only one of the advantages ensuing therefrom

A GREAT deal of interesting matter on the methods and practice of boundary determination and demarcation is contained in *Bulletin* 817 of the United States Geological Survey, entitled "Boundaries Areas, Geographic Centers and Altitudes of the United States and the Several States" The history and the methods of marking the boundaries are given for all the States and for the international frontiers In several cases a lack of understanding of physical geo

graphy led to boundary disputes and readjustments, as in the case of the shifting bed of the Rio Grande between Texas and Mexico, or the Alaskan boundary dispute of 1898 The pamphlet contains also a great deal of statistical matter and several maps Of the latter, the most interesting is a large reproduction of the Mitchell map of British and French dominions in North America in 1755, on a scale of about fifty miles to an inch

PROF R F GRIGGS, of George Washington University, has recently returned from a botanical expedition to the Katmai volcanic region of Alaska (*Daily Science News Bulletin*, Science Service, Washington, D C) About twenty years ago, Katmai practically exploded and devastated a great area of country, which was left covered with volcanic ash This covering was almost devoid of nitrogen, and Prof Griggs has paid special attention to the plants which first populated this bare and arid soil The first plants were liverworts, and although there is little or no nitrogen in the soil, it is, of course, present in the plants themselves It is not clear at present whether the liverworts have the capacity to take nitrogen from the air themselves, or whether this power is associated with some fungus growing in close association with them Such close mycorrhiza like union of a fungus with a liverwort has been described on several occasions Prof Griggs proposes to study the question further on this group of plants, in the laboratory

DR WILLEM DE SITTER, director of the Observatory at Leyden, has been awarded the Catherine Wolfe Bruce gold medal for 1931 of the Astronomical Society of the Pacific "for distinguished services to Astronomy "

THE special exhibition at the Imperial Institute South Kensington, of the mineral resources of the Empire, which was noted in NATURE, Feb 14, p 248, will remain open until April 30 In connexion with this exhibition, Sir Edwin Pascoe, director of the Geological Survey of India, will give an address on The Mineral Wealth of India ", on Mar 12, at 5 30 P M Tickets for seats may be obtained from the Secretary, Imperial Institute, South Kensington, S W 7

THE fifth general meeting of the 'Dechema' (Deutsche Gesellschaft fur chemisches Apparatewesen) will be held, with that of the Verein deutscher Chemiker, in Vienna, on May 28 and 29 The subject chosen for the symposium is "The Separation of Solid and Liquid Substances" Offers of contributions should be sent in not later than Mar 15, to the head office of the 'Dechema', Seelze b Hannover

DR E R WEIDLEIN, director of the Mellon Institute of Industrial Research, Pittsburgh, Pa, has announced the appointment of Dr L H Cretcher to an assistant directorship in the Institute Dr Cretcher, who, since 1926, has been serving as head of the Institute's Department of Research in Pure Chemistry, will be in charge of a group of industrial fellowships concerned with problems in organo chemical technology Dr Cretcher was formerly a member of the organo-chemical division of the Rockefeller Institute, and in 1919 took up a research post in the laboratory of the National Aniline and Chemical Company He is best known for his work on sugar chemistry He has also contributed to the knowledge of pyrimidine aldehydes, oxidation of tertiary hydrocarbons, glycol ethers and esters, organic boron compounds, barbituric acids, chloro ethers, and equilibria in binary liquids systems

WE have received from the Association of British Chemical Manufacturers 166 Piccadilly, London, W 1, a well bound volume of 405 pages entitled "British Chemicals and their Manufacturers", which is printed in English and five other languages, French, Spanish, Italian, Portuguese, and German All the entries are classified under products in separate indexes in these languages There is also a section dealing with products under proprietary and trade names, the nature of the product being stated in the languages mentioned The volume may be obtained gratis by genuine users of chemicals on application to the Association at the address given above

A CATALOGUE (No 15) of upwards of 300 second hand works on botany, horticulture, zoology, and geology has just been issued by Mr J H Knowles, 92 Solon Road, S W 2

THREE short lists (B 7, B 8, and B 9) of second hand books on, respectively, botany, gardening and agriculture, natural history, and angling, fish and fishing have just reached us from Messrs Francis Edwards, Ltd, 83 High Street, Marylebone, W 8

APPLICATIONS are invited for the following appointments, on or before the dates mentioned -A junior research assistant in the department of chemical technology of the Imperial College of Science and Technology—The Registrar, Imperial College of Science and Technology, South Kensington S W 7 (Mar 12) A sub inspector of quarries in the North Midland Division of the Mines Inspectorate of the Mines Department—The Under Secretary for Mines, Establishment Branch, Mines Department Dean Stanley Street, S W 1 (Mar 16) A chemical assistant to the advisory chemist of the School of Agriculture, Cambridge - The Secretary, School of Agriculture, Cambridge (Mar 19) Lecturers in, respectively, geography and mathematics and physical training and hygiene, at St Hild's Training College, Durham—The Principal, St Hild's Training College, Durham (Mar 20) A full time lecturer in civil and mechanical engineering at the Polytechnic, Regent Street—The Director of Education, The Polytechnic, Regent Street, W 1 (Mar 20) An assistant secretary under the Middlesex Education Committee, having special knowledge of technical education and with experience in courses leading to national certificates in electrical and mechanical engineering and in building construction—The Secretary, Education Offices (H), 10 Great George Street, S W 1 (Mar 21) A professor of economics in the Panjab University—The Secretary, Universities Bureau, 88A Gower Street, W C 1 (Mar 28) A director of the Research Institute of the Rubber Research Scheme of Ceylon—

The Chairman of the Board of Management, Rubber Research Scheme, Peradeniya, Ceylon (Mar 30) A deputy director of the Public Health Laboratories, Cairo—The Under-Secretary of State, Department of Public Health, Cairo (April 14) A demonstrator in physics at Bedford College for Women—The Secretary, Bedford College for Women, Regent's Park, N W 1 (April 20) A lecturer and adviser in veterinary science in the Harper Adams Agricultural College and National Institute of Poultry Husbandry—The Principal, H A A C, Newport, Shropshire

ERRATUM —NATURE, Feb 21, p 268, five lines from end of notice of "The Economics of Forestry" by W E Hiley for "British Isles" read "British Empire"

Our Astronomical Column

Mapping the Larger Magellanic Cloud —A recent *Daily Science News Bulletin* issued by Science Service, Washington, D C, gives a summary of a paper by Prof H Shapley read before the American Association for the Advancement of Science at the recent Cleveland meeting, he stated that a detailed map of the larger cloud is being prepared, the cloud contains 200,000 giant and supergiant stars, each more than 150 times as bright as the sun, and more than 2000 stars that are each more than 10,000 times as bright as the sun

Another *Bulletin* gives a new estimate of the distance of the sun from the centre of the galaxy Dr Harlow Shapley had found a distance of 15,400 parsecs by taking the mean of two different methods, but, since that was made, Dr R J Trumpler has found evidence of appreciable absorption of light in the galactic plane, Dr van de Kamp has applied the necessary correction to Dr Shapley's figures, and finds that the distance is reduced to some 12,000 parsecs, or even less

The Eighth Satellite of Jupiter —This tiny body the magnitude of which is 17½, has been unobserved since June 1923 It was discovered by Mr Melotte at Greenwich in 1908, and was followed there for many years, but of late years the Thomson Equatorial, which is the only instrument there that is suitable for observing it, has been in use for stellar parallax and other researches There was danger of its being lost, as the solar perturbations are very large and the computation of them long and tedious However, Prof Numerov, of Leningrad, computed them a few months ago, and issued an ephemeris, Prof G van Biesbroeck has succeeded in photographing the satellite, and publishes eight positions, obtained from photographs on four nights, in *U A I Circ* No 310 The first position is

	R A (1930 0)	N Decl
Dec 16 20562 U T	$7^h\ 25^m\ 36\ 46^s$	$22°\ 54'\ 50\ 3''$

The observed places are about 8 sec smaller in R A than the predicted ones, and 10′ north of them These residuals are satisfactorily small after an interval of nearly eight years The plates were taken with the 24 inch reflector at Yerkes, with an exposure of 30 minutes

Variable Stars in the Globular Cluster Messier 3 (Canes Venatici) —*Astr Nach*, No 5747, contains a study of the light variations of 47 stars in this cluster, by Mr Paul Slavenas The plates used were 97 in number, and were taken by Dr J Schilt in 1926 with the 60 inch reflector at Mt Wilson The data for 30 stars were sufficient to deduce accurate periods these are given to the eighth decimal of a day, the shortest is about 0 288 day, the longest 0 708 day The majority lie close to half a day It will be remembered that it was from a study of the magnitudes and periods of Cepheids that the distances of globular clusters, the Magellanic Clouds, and the spiral nebulæ have been determined

Reference Stars for the 'Selected Areas' —The scheme, initiated by the late Prof Kapteyn, of intensive observations of stars, both bright and faint in certain areas distributed uniformly over the entire heavens, needs very careful meridian observations of the brighter stars in each area, since these have to serve as reference points for the plate constants, and the proper motions of the faint stars will depend upon them The Observatory of Leyden has just produced a catalogue of 1172 of these stars in vol 15, part 3, of its *Annals* They include all the 'areas' in the northern hemisphere except the polar one The catalogue bears the names of C H Hins and J J Raimond, jr, with Prof de Sitter as director The observations were made between 1921 and 1929 In 1922 a hand driven moving wire micrometer was inserted As there is no movable declination thread, the declinations were observed at different times from the Right Ascensions, the eye-end of the telescope being turned through a right angle Most of the stars have been observed at least twice in R A and three times in Declination The positions are reduced to the equinox of 1925 0

Occultation of Antares —Kwasan Observatory *Bulletin* No 189 contains an observation of the occultation of Antares on Jan 15 by Prof K Nakamura with the 30 cm Cooke refractor It was cloudy for the disappearance At the reappearance, the greenish companion emerged first, and the bright star some 4 seconds later It was seen first as a dim red glare, and took fully a tenth of a second to reach full brightness This is in good accord with the large diameter of the star, about 0 04″, found by the Mount Wilson interferometer The times of emersion in U T are

1931 Jan $14^d\ 20^h\ 2^m\ 27^s$ companion
30 9 Antares

The first time is noted as probably late

It is of interest to note that the first observation of the companion was made on the occasion of an occultation The *Berliner Jahrbuch* of 1822 records that Burg at Vienna observed the small star reappear five or six seconds before the bright one on April 13, 1819 He concluded that Antares is double Bode, however, discredited this, and added the note, "Antares ist kein Doppelstern" The companion was not seen again until 1844 (by Grant in India) and 1845 (by Mitchel in America) Incidentally the green colour of the companion is shown to be inherent, not a contrast effect, when it reappears before the bright star

The Cracow Astronomical Handbook for 1931 —This handbook, as usual, is almost entirely taken up with ephemerides of variable stars There are 391 eclipsing variables for which the dates of minimum are given, and 382 others for which certain elements are given There are also elements of occultations of stars by the moon for several stations in Poland There are also useful tables of precession, obliquity of ecliptic, etc The explanations are given both in Polish and in flexible Latin, which is very easy to read.

Research Items

Food Supply of India—In the presidential address delivered to the agricultural section at the seventeenth meeting of the Indian Science Congress at Allahabad (Calcutta · Asiatic Society of Bengal), G Clarke discussed the necessity of increasing the food supply to meet the needs of the growing population in India From a consideration of the agricultural returns for 1922–23 and 1925–26, it is evident that the area available for food production in India is 1 2 acres per unit population, whereas in America and France, countries comparable with India as regards the importance of agriculture, the corresponding figures are 2 6 and 2 3 respectively The amount of new land in India suitable for cultivation is no longer sufficient to provide the increased area required, so that the solution of the problem lies in increasing the yield of the land already in use Weather conditions and the shortness of the growing season are the chief difficulties confronting the agriculturist, but the use of modern methods of research, and in particular a closer study of the critical periods of crops, that is, those intervals during which the plant shows maximum sensibility to external factors such as moisture or nitrogen supplies, should do much towards the attainment of better results Further, green manuring is particularly advocated as an economical means for soil improvement and the maintenance of an adequate nitrogen supply From a comparison of conditions in other countries and analogy with the progress of the sugar cane industry in India, it is possible to obtain a rough estimate of the increased production likely to follow the application of scientific methods to agriculture After making due allowance for the inevitable lag in the adoption of improvements, and taking into consideration the abundant labour resources and responsive nature of the soil in India, it is thought that within the next two or three decades an increased output of 30 per cent in normal seasons may reasonably be expected Increased expenditure on scientific research is, however, assumed

Bionomics and Morphology of *Paraphædon tumidulus*– The intensive study of an organism is useful in entomology By making facts of structure known, it places in the hands of the morphologist material with which he can arrive at ideas of truer relationships It also serves as a means of giving clues of weak points in the insect's anatomy which may be used by the economic entomologist to bring it under control, if it is injurious in any way Dr Nellie F Paterson's recently published paper entitled "The Bionomics and Morphology of the early stages of *Paraphædon tumidulus* Germ" (*Proc Zool Soc*, Oct 22, 1930, pp 627-676) is an effort of this nature The insect belongs to the Chrysomelidæ—a large family of beetles which are all phytophagous, and consequently many of them are serious pests of cultivated plants The study was made in the zoological laboratory of the University of Cambridge while the author was holding a scholarship awarded by the University of the Witwatersrand, Johannesburg The study contains notes on geographical distribution, food plants and nature of damage, and details of life-history The exoskeleton and the internal anatomy are reviewed in great detail The paper is illustrated by four plates and seventeen text-figures An interesting feature is that the author has formulated a system of enumeration and nomenclature of the larval chætotaxy Although it may apply to some Chrysomelid larvæ, it cannot be a comprehensive scheme which would embrace the whole family Dr Paterson is to be congratulated on her fine study

An Australian Myriothela—E A Briggs (*Rec Austr Mus*, Sydney, **18**, 1930) gives an account of the salient features in the histology of *Myriothela harrisoni* from the coast of New South Wales The ectoderm of the hydranth is described as stratified, the supporting lamella is thin and from its outer surface extend simple or branched secondary lamellæ, on each side of which the well developed longitudinal muscle fibrils of the ectoderm are situated The endoderm presents the usual types of cells—goblet, gland, vacuolate, and storage The tentacles of the hydranth are remarkable for the extraordinary development of the supporting lamella in the capitulum where it is produced into radially arranged fibres which form the main mass in the apex of the tentacle The fibres keep this part of the tentacle expanded when the remainder is contracted The blastostyles, which are borne on the middle zone of the hydranth in such numbers as to hide the surface, are mouthless, and each is continued into a single terminal tentacle The mature gonophores borne on any one individual are of the same sex, both male and female gonophores have an apical opening representing the velar aperture

Biological Control of the Prickly Pear—Several species of *Opuntia* have spread very widely in Australia since their accidental introduction, and two species, *O inermis* and *O stricta*, have become very serious pests In 1912, the Queensland Government appointed a commission to investigate the natural enemies of these plants, and since 1919 the Commonwealth Government has co operated with Queensland and New South Wales, the work of searching for natural enemies of the prickly pear in its natural haunts being placed under the control of the Commonwealth Prickly Pear Board The whole of the cactus belt in the United States was examined, and some seventy different kinds of insects were found on the prickly pear Under the title, "Ten Years' Research on the Prickly Pear", C Schindler, of the University of Brisbane, gives an account of this work in *Discovery* for February Very striking success appears to have accompanied the introduction of the moth, *Cactoblastis cactorum*, which was found in La Plata in 1914, and re discovered in the Argentine and Uruguay in 1925 A shipment of eggs reached Australia safely in 1925 and was an immediate success The caterpillar tunnels in the fleshy stem and, living gregariously inside this spine covered fleshy mass, is protected against birds Schindler estimates that the area covered by the prickly pear in Australia is now being reduced by one million acres a year, as a result of the various methods of biological control now in use, instead of this pest spreading to about the same acreage of new country each year, as was formerly the case This Australian work will have considerable interest for other countries, for example, South Africa

Spiral Ringing and Solute Movement in Trees—Profs L H McDaniels and O F Curtis have published the results of their latest experiments on the ringing of trees in *Memoir* 133 of Cornell University Agricultural Experiment Station (October, 1930, 31 pages) The results refer mainly to the spiral ringing of apple trees, and the findings confirm the opinion of these workers that the phloem is the tissue most concerned in translocation, handling solutes taken in by the roots and foodstuffs elaborated in the leaves Photographs showing the effect of spiral ringing in increasing the fruitfulness of apple branches are given,

and the practice of tapping trees for oleoresin is also reviewed Lateral transference of solutes and foodstuffs in the trunk is shown to be slow, immediately after the ring has been made It is suggested that the meeting of the downwardly moving foodstuffs and the upwardly directed solute current causes an electrical polarity of the cells at the junction, that is, the incipient cambium, and the responses of plants to such practices as propagation, pruning, and grafting are discussed from this point of view The regeneration of the tissues following ringing has been studied, and leads to the conclusion that translocation rapidly becomes normal after the wounding

Selection of Maize for Germination and other Tests —Mr R C Malhotra, of St Mary's College, Kansas, writes to say that in germination tests of maize seedlings he finds that the irregularly shaped seeds taken from the tip and butt ends of the ear, especially those in which the embryo is located at the side of the seed, seldom if ever germinate The use of such seeds, even if of heavy weight, may cause an experimental error of 20 25 per cent in germination In the middle of some ears a number of compressed, thin, undeveloped, and starved seeds may be found They germinate promptly, probably because of the thin pericarp, but produce poor, under nourished seedlings and should be excluded from germination experiments In experiments with X rays and ultraviolet light, the effect of exposure is very different according to which side of the seed is exposed, as the embryo is much nearer one side than the other The embryo side should be exposed for uniform results

The Theory of Isostasy — In a critical review of isostasy by Hubbert and Melton, appearing in the *Jour Geol*, pp 673–695, 1930, the underlying theory is very clearly summarised, and special attention is directed to Hopfner's recent inquiry into the problems involved Hopfner claims that the observed gravity anomalies can be accounted for, without recourse to the principle of isostasy, by taking into consideration the effect of elevation and depression of the geoid relative to the spheroid of reference (Brun's term) These effects lead to the conclusion that gravity ought to be deficient over the continents and excessive over the oceans, as indeed it is, this being the leading fact that isostasy has been invoked to explain The authors state that although the results of Hopfner are admittedly qualitative, "they are of sufficient importance to cast a large shadow of doubt over the whole of isostatic theory" Against this depressing conclusion there appears simultaneously an important paper by Heiskanen in the *Am Jour Sci*, Jan 1931, pp. 39-50 It is admitted that the reduced gravity values g_0 are referred to the geoid, whereas the theoretical values γ are referred to the spheroid, but several lines of evidence are presented to demonstrate that gravity anomalies could be explained by Brun's term only if its quantitative value were about ten times greater than it actually appears to be Heiskanen concludes that Hopfner's arguments are founded on a qualitatively correct basis, but that he has greatly exaggerated the influence of the effects deduced Readers of the first paper referred to above should on no account omit to study the second Taken together, they provide a most illuminating account of an intricate subject that is rarely clearly understood

Gas in Relation to Oil Production —B J Ellis discussed this subject at the meeting of the Institution of Petroleum Technologists last December, and, in effect, gave a very practical interpretation of S C Herold's well-known recent work on simple perfect fluids and their mechanics As he (Mr Ellis) pointed out, Herold's thesis deals in the main with ideals—perfect gases and liquids in homogeneous reservoirs, and although the principles enunciated have obvious application to oilfield circumstances, such conditions cannot be realised in actual practice The author proceeded to examine the concrete variables, the gas, oil, and the reservoir, as existing in Nature, and thereafter sought to modify Herold's theories in terms of actual conditions Such a study is bound to bring in its train the more practical questions of repressuring oil pools and gas drive, and some attention was devoted to these aspects of field development, while a possible method of increasing the recovery of petroleum by a modified form of gas drive was indicated In this latter conception is probably the most interesting part of the paper What is known as 'centripetal production' was shown to be one of the best means of obtaining more oil from a reservoir from which utmost production had been obtained by normal methods, a means apparently applicable, at least in theory, to virgin production Briefly, centripetal production implies the injection of gas by wells specially drilled for the purpose at geometrical points determined by the positions of output wells and their circles of influence, injection should take place at a pressure equal to or slightly higher than the original reservoir pressure

River Flow Records in the Ness Basin, Inverness shire —Previous notice has been given in NATURE (Mar 1 and 29, 1930, pp 334, 514) at some length of the series of observations of river flow in the Ness Basin, Inverness shire, made in 1929 by the voluntary organisation known as River Flow Records, under the direction of Capt W N McClean, of Parliament Mansions, Victoria Street, S W 1 These observations have since been extended to cover the period from January to September inclusive, 1930, and the results relating to the river Garry are embodied in three quarterly reports recently issued The reports show that during the period in question, in addition to rainfall observation, there have been five months actually spent on river gauging work, with the design and construction of new gear for flood measurements and the erection and maintenance of water-level gauges Much useful and interesting data have been acquired and, for local, and even general reference, the statistical tables will be of great value The latest of the three reports provides an opportunity of comparing the flow and period losses of the two rivers, Garry and Moriston, over a full twelve months period, from which it may be noted that while both have catchment areas of 150 square miles, the twelve months' flow off of the Moriston is about 73 per cent of that of the Garry The 'period losses' in each case were fractionally above and below 14 inches The report concludes with some comments on the organisation required to maintain these records of flow after the actual gauging work is completed

A Gyroscopic Clinograph —Another interesting application of the gyroscope is the subject of an article entitled "Oil Well Surveying with the Gyroscope", in the November issue of the *Sperryscope*, the organ of the Sperry Gyroscope Company, Inc In the boring of oil wells many things lead to a deflection of the path of the drill from the vertical, and it is important to the driller that he should be informed of any such deflection There are several methods by which the angularity of an oil well can be determined, and some success was obtained with the use of the magnetic compass In conjunction with the Sun Oil Company, the Sperry Gyroscope Company has now brought out the 'Surwel' gyro

scopic clinograph. In this apparatus are incorporated a gyroscope with its axis set north and south, a box-level gauge, a chronometer, and a film camera, these parts being contained in a steel cylinder $5\frac{1}{4}$ in. in diameter, which can be lowered down the well. The bubble in the box level shows the inclination, a pointer on the gyroscope gives the direction of the inclination, while the camera, timed by the chronometer, takes a series of photographs of bubble, pointer, and chronometer hands. As the rate of lowering is known, the exact depth at which each camera observation is made can be found, and thus the inclination and its direction can be determined at any given depth. The data recorded on the film can also be plotted on squared paper and a graphic picture of the well's course through the ground can be obtained.

Loud Speaker Acoustics.—The design of commercial loud speakers is largely empirical and, indeed, a complete theoretical treatment of the problem is not yet possible. A number of important factors affecting the reproduction of speech and music by coil and reed driven speakers are discussed in a paper by N. W. McLachlan and G. A. V. Sowter (*Phil. Mag.*, **11**, pp. 1-54). It is shown that a *rigid* coil- or reed-driven disc system would be of little value in the reproduction of either speech or music. The energy from the coil-driven disc decreases very rapidly above 1000 cycles, whereas the energy from the reed-driven disc is centred round the resonance frequency of the combination. A reed-driven *flexible* disc fails as a reproducer, owing to prominent, widely spaced, natural frequencies due to the limited number of modes of vibration of the disc in the audible frequencies. Actual coil- and reed-driven diaphragms give better reproduction than would be expected from the rigid disc theory, and they possess an almost continuous succession of minor resonances. The theoretical conclusions are supported by experimental evidence. Measurements of the radial velocity of sound in discs were made, and it was found that near the periphery of a conical diaphragm the velocity is considerably less than in air. A summary of sixteen electrical, acoustical, and mechanical factors causing distortion in the reproduction by moving coil systems is given at the end of the paper and indicates the extreme complexity of the problem.

Records of Slow Electrons.—In a paper by P. H. Carr in the December number of the *Review of Scientific Instruments* an account is given of a very promising method for recording slow electrons of energy less than 100 electron volts. A piece of metal, which may be either in a massive form or a sputtered film, is mounted in the vacuum apparatus, in exactly the same position as a photographic plate would be. After exposure to the beam of electrons, the speed of which is readily controlled by magnetic sorting, the metal is treated chemically, when, with the appropriate reagents, a visible trace of the area of impact appears. Gold, silver, and zinc have been studied in the greatest detail; the best developing agents for the latent images were found to be mercury, iodine, and hydrogen chloride respectively, all in the vapour phase. Gold gives the greatest contrast if the images are to be reproduced afterwards by ordinary photography, but with silver striking colour effects can be produced, which are especially useful for demonstration of the effect. Zinc is the least trustworthy of the three metals, but when images are present on it, they are of excellent definition. It appears that although the technique involved is rather laborious, yet the method is less liable to failure with the slowest electrons than ordinary photography, whilst it has the great advantage that it is not subject to interference from light, either extraneous or from hot filaments within the apparatus.

Isotopes of Beryllium.—The element beryllium occupies rather an anomalous position in that it appears to be a simple element of mass 9, although, from the properties of other elements, it might be expected to have an isotope of mass 8. Evidence for the existence of this isotope has now been found by W. W. Watson and A. E. Parker, from a study of the band spectrum of beryllium hydride in the neighbourhood of 5000 A. (*Physical Review*, vol. 37, Jan. 15). When this is photographed in the third order of a 21 ft. concave grating, giving a dispersion of 1.3 A. per millimetre, every main line in a certain region is found to be accompanied by a weak satellite, and taking the main lines to be due to the molecule Be^9H, the satellites can be shown to be in the positions appropriate to Be^8H. The relative intensities of the Be^8H lines and the Be^9H lines are about 1 to 2000. These results, if substantiated, will confirm Lord Rayleigh's suggestion, which is based on the occurrence of unusually large quantities of helium in the mineral beryl, that a Be^8 nucleus is less unstable than has hitherto been supposed.

Organic Selenium and Tellurium Compounds.—The January number of the *Journal of the Chemical Society* contains two papers by Morgan and Burstall on *cyclo*-selenohexane and *cyclo* tellurobutane respectively. *Cyclo* selenohexane, containing Se interposed between two CH_2 groups in *cyclo* hexane, is a pungent smelling oil, obtained in small yield by the action of sodium selenide on $\alpha\zeta$ hexamethylene dibromide in alcoholic media, the main product being a mixture of at least two polymeric forms. It gives a crystalline mercurichloride, $C_6H_{12}Cl_2SeHg$, a dichloride, a dibromide, a di-iodide, and a methiodide, by direct addition. *Cyclo* tellurobutane, a five membered ring compound, was obtained by the interaction of tellurium with $\alpha\delta$-tetramethylene di-iodide at 130°, giving the *cyclo* telluributane di-iodide, which can be reduced to *cyclo*-tellurobutane, a pale yellow oil of repulsive odour which oxidises rapidly in air, the tellurium atom taking up an atom of oxygen. The cyclic tellurohydrocarbon forms very stable dihalides, the chlorine and bromine compounds crystallising unchanged from water. A mercurichloride and a methiodide were also prepared.

Distortion of Flame Surfaces in Electric Fields.—Guénault and Wheeler, in the January number of the *Journal of the Chemical Society*, describe some experiments on the effect of an electric field between two parallel metal plates on the propagation of a carbonic oxide flame initiated at the centre of a spherical bulb. The paper contains some excellent photographs of the flames produced, which show a decided effect of the field. There appears to be little or no alteration in the rate of growth of the flame in a direction transverse to the field. The field did not stimulate the growth of the flame between the plates in the direction in which electrons produced in the flame would be moving, so that such electrons do not appear to assist the propagation of the flame. The speed of the flame was, however, increased in the opposite direction, in which the positive ions are moved. There was also a bodily movement of the whole of the spherical flame surface in the same direction, and sometimes wholly away from the igniting spark. The movement in the opposite direction is, therefore, not only retarded but actually reversed by the field. This suggests that the movement of the flame surface may be mechanical, due to the movement of the heavy positive ions dragging the flame surface with them, and not necessarily the result of a stimulus to chemical activity imparted by the electric field.

Russian Scientific Workers in Foreign Laboratories.

NEVER before in the history of science has there been a case when hundreds of scientific workers have been exiled wholesale from their country, or have left it because they have found it impossible to continue scientific work there This is what happened in Russia after the Bolshevist revolution took place about ten years ago, scientific workers, with others, either had to submit to the new régime with its somewhat unusual views on the subject of the free dom of scientific thought, or to try to seek their fortunes elsewhere There are no statistics to tell us of the many who left their life's work and their homes behind them, only to fail in their hazardous attempts and to go down in the struggle for existence, but it is of great interest to learn that a large number of them succeeded in finding suitable occupation in various countries and have been able to continue their studies A good idea of their work can be obtained from the bibliography of books and papers published by Russian scientific workers abroad during the period 1920–1930, issued recently by the Russian Scientific Institute founded in Belgrade with the active support of the Jugoslavian government *

The volume contains no less than 7032 titles of books and papers published in 18 different languages by 472 Russian authors scattered all over the world, from Sofia to Stockholm, from Kharbin and Indo China to London and Paris, and from Chicago to Rio de Janeiro It is natural that the bulk of the titles are those of works on economics, sociology, history, philology, law, and other branches of the humanities, as well as engineering and other applied sciences, but there is an unexpectedly high percentage of works on the natural and exact sciences Their number is 1929 and they belong to 122 authors The list is headed by 596 works written by 38 authors on various prob lems of medicine and physiology, and an important place amongst them belongs to several former pupils of the famous I Pavlov, whose methods for the study of the physiology of the nervous system are now being developed by them in a number of laboratories in Europe and in the United States Nine Russian botanists published 121 works, amongst which the books of V V Lepeshkin on the chemical physiology of plants are well known to specialists Exiled geologists number 11, and there are such celebrities amongst them as the late N I Andrusov (Prague) and A Stebutt (Belgrade), the aggregate number of publications on geology reaching 102

* Materialy dlya bibliographii russkich utchenych trudov za rubezhom (1920–1930) Part I pp 394 Belgrade, 1931

Ten Russian zoologists and entomologists produced 250 books and papers, including a series of outstanding articles on comparative anatomy by M M Novikov (Prague), culminating in the book "Das Prinzip der Analogie und die vergleichende Anatomie" (Jena, 1930) Amongst entomological works, the world catalogue of Aphaniptera by J N Wagner (Belgrade) should be mentioned Microbiologists are only three in number, but the name of S Metalnikoff (Paris) will be familiar to most specialists in this branch, and the 115 papers produced by them represent a valuable contribution to a number of fundamental problems Russian chemistry, too, can be justifiably proud of the work of J I Bickermann (Berlin) and E Rabinovitch (Göttingen), to mention only two of the 13 chemists with their 133 publications, while 6 physicists published 101 papers, and 200 papers and books on mathematics and mechanics have been pro duced by 11 Russian workers There are only two Russian astronomers abroad, but their names are O Struve (Chicago) and V Stratonov (Prague), and they published 100 papers between them To com plete the list, 131 papers and books on geographical subjects written by 11 authors, and 80 publications by 9 authors on agriculture, appeared during the period under review

Striking though these figures are, they are very in complete, because the bibliography included only the works of those Russian scientific workers who sub mitted lists of their papers, many of them failed to do so for various reasons The editors, however, hope to publish supplements to the bibliography from time to time

It will be seen that many Russian scientific workers made full use of the opportunities offered them at various universities and laboratories, most of which have gladly opened their doors to their Russian colleagues

Apart from contributing to the progress of science by their own original work, Russian scientific workers are also doing a great service to men of science of other nations by making available to them the results of Russian researches, which remained largely unknown abroad, by reviewing current and past Russian literature in the respective fields It would probably not be an exaggeration to say that practically every bibliographical, or abstracting, periodical has now Russian experts on its staff, and this helps to make Russian scientific work available everywhere

B P U

The Constitution of Soluble Proteins.

THE *Comptes rendus des travaux du Laboratoire Carlsberg*, vol 18, No 5, 1930 (Copenhagen H Hagerup, 1930. 6 25 Kr), contains a long paper (in English) by Prof Sørensen on recent work on the soluble proteins considered in the light of his theory of reversibly dissociable component systems According to this, soluble proteins consist of a series of complexes or components, reversibly combined, A_x, B_y, C_z , these components being, for example, mainly polypeptides, but in other cases containing phosphorus, in each of which the atoms are linked by principal valencies, whereas the complexes them selves are held together comparatively loosely and reversibly by residual valencies The strength and nature of these residual valencies depend on the chemical composition of the component in question as well as on its physical properties—above all on its dimensions and the resulting shape and surface

Alterations in the composition of the solution (salt content, *p*H, alcohol content, temperature) may give rise to reversible dissociation of the component systems and interchange of components between them When these alterations in composition are so suited as to render possible the formation in sufficient quantities of a component system insoluble or spar ingly soluble under the new conditions, such a system will be formed and precipitated

It is not always easy to determine whether a given protein solution is a mixture or a true componen system Prof Sørensen shows that the results of hi investigations and his theory of reversibly dissociabl components are reconcilable with Svedberg's result on the molecular weights of proteins as found b the ultra-centrifuge method These show that onl a few proteins have molecular weights exceeding million, namely, the haemocyanins of the blood o

some snails The molecular weights of other proteins are, with one exception (casein, which contains protein molecules of various sizes), small multiples of about 35,000 Egg albumin and Bence Jones's albumin belong to the first group, with spheroidal molecules of radius 22 A and molecular weight 35,000 Hæmoglobin and serum albumin have non spheroidal molecules of weight 70,000, serum globulin belongs to the third group, with non spheroidal molecules of weight 105,000, and the fourth group, with spheroidal molecules of radius 40 A and weight 210,000, includes the vegetable proteins edestin, excelsin, and amandin The results for egg albumin, by very different methods, are unanimous, and everything seems to show that it is a simple chemical unit Serum albumin, on the other hand, has been fractionated Although the results of Svedberg and Sjögren gave a molecular weight of about 67,500, instead of the value 45,000 found by Sørensen, the latter does not think his product contained true decomposition products, since the fractions retained their marked power of crystallisation He considers that reversible dissociation only had occurred He makes a far sharper distinction, in this and other examples, between reversible dissociation and true decomposition of a protein than does Svedberg

The nature of peptic scission is considered at length, the conclusion being reached that the breaking of peptic linkages is the sole chemical process involved, the simultaneous marked change in physical properties being due to secondary processes (hydration and disaggregation)

The name 'component systems' is now preferred to that of 'co precipitation systems' introduced by Linderstrøm Lang, the name 'component' being used for an individual reversibly linked constituent The real character of the molecular weights found by Svedberg is accepted, and the 'average molecular weight' found for a mixture can give valuable information

In the experimental part, emphasis is laid on the importance of determining the distribution of the components of the dispersion medium between the solution and the undissolved phase, and a number of examples from previous memoirs, as well as new investigations, are summarised in this section Some tendency to reversible dissociation was detected with egg albumin Serum albumin was separated into three groups of fractions differing in solubility, irrespective of whether the fraction in question is phosphorus containing or not The various fractions differed very little in chemical composition, and two almost identically composed substances may be widely different in solubility, a result which is not due to denaturation Casein has a very considerable tendency to dissociation, but is not regarded as a mixture Its ionisability in presence of acid or alkali gives rise to component systems with a much greater dissociating tendency than that of uncharged or isoelectrically charged systems

The question of protein systems in serum is considered They are regarded as in continual mutual interaction, forming new systems, the composition of which depends on concentration and other conditions, and the proteins may not correspond with those precipitated by salts The question which this suggests, whether it is reasonable to retain the old terms serum albumin and serum globulin, is considered, the answer being in the affirmative

The interesting relation between lipoids and proteins in serum is discussed, particular attention being given to Mâcheboeuf's experiments The latter obtained from horse serum a product which he regarded as a chemical compound of lecithin, cholesterol ether, and protein, from which lipoids cannot be extracted by ether, and in which the protein is not, or is only slowly, denatured by alcohol at the ordinary temperature This conclusion is accepted, and it is suggested that the perfect clearness of such liquids as serum and plasma, in spite of their high lipoid content, is explicable only by assuming linkages between the lecithin and sterols on one side and the proteins on the other The linkage between lipoid and protein is weak and may be split in emulsification processes, a real chemical linkage is not probable

It will be seen from the above brief summary that Prof Sørensen's authoritative memoir raises many questions of considerable interest and importance, both from the chemical and the biological points of view, and it may be welcomed as a brief yet comprehensive summary of recent work in that branch of protein investigation to which its author has made so many important contributions

General Biology in the "Encyclopædia Britannica"

ANY criticism of the articles on general biology in the "Encyclopædia Britannica" must take into consideration, first, the fullness and accuracy of the information contained in them, and secondly, the mode of presentation For it is surely not sufficient to provide a summary, however authoritative, of any branch of science, if this is presented in such a manner that it cannot be understood by the general reader It is for his benefit that the "Encyclopædia" is, presumably, issued, and its financial success is certainly dependent upon his willingness to purchase it

There are some branches of physical science in particular which cannot be presented to the public in an intelligible manner Both the subject matter and language employed are alien But this has not in the past been true of biology Here the general reader has felt confident of understanding articles written about it It is in some degree a measure of the very definite advance which biology has made in the past generation that the general reader will not infrequently find these biological articles difficult of comprehension But the fault does not always lie solely in the subject matter, for several of the authors have shirked the admittedly difficult task of presenting their information in plain English and taken the easier way of scientific 'shorthand' The more intricate biology becomes, the greater the need for clear writing in articles such as these

It is pleasant to find, therefore, that the articles which will probably be most frequently consulted by the general reader, evolution by Prof E S Goodrich and zoology by Prof D M S Watson, are wholly admirable in both their scope and presentation No biologist can read them without having his ideas clarified, and no layman can fail to understand them or to be impressed by the range of knowledge they display The only criticism we have concerns the article on evolution Here the vital need, in Darwin's opinion, of natural selection as the mechanism which prevented the swamping, as he thought, of any favourable variation by promiscuous interbreeding, is not stated The reader is left with the impression that Darwin realised, as his successors do to-day, that there was such a thing as segregation which makes swamping impossible

Prof J B S Haldane has made the best of a very difficult task in his article on heredity It is not easy reading, but, in view of the nature of the facts with which it deals, this could not be avoided, and the

reader who takes the trouble to work his way slowly and carefully through this article will be repaid by the acquisition of a clear idea of the present state of knowledge on this subject, and also with a respectful feeling that biology *is* developing into an exact science The article is a thorough-going account of the modern developments of Mendelism, but, with all possible respect to the work which it summarises, one is left with a feeling of the immensity of the super structure which is now borne on the shoulders of the chromosome theory, and with a doubt as to whether some future edition of the "Encyclopædia" may not contain accounts of underlying principles of heredity as yet unsuspected

Prof F A E Crew also provides an excellent summary of modern knowledge on sex, but, with somewhat more tractable material at his disposal, he is not quite so successful in his presentation By some oversight, his long article contains no illustrative diagrams or graphs It is doubtful whether the general reader, however painstaking, will really acquire a clear idea of the subject from this article, but to the biologist it can be recommended as a masterly summary of the facts

Two articles, one on ecology by Mr C S Elton and the other on experimental embryology by Mr G R de Beer, bear testimony to the development of work on these subjects of recent years The general reader will find Mr de Beer's article full of surprising and unexpected information, and few biologists, outside the limited number who work on this subject, will fail to profit by the reading of it Mr Elton's article is interesting and well written but rather surprisingly long—the result, not of excess of knowledge, but of too little and a consequent lack of summarising generalisations But it is a little difficult to understand why this article should be so long, when Prof C Lloyd Morgan is so restricted in his article on animal behaviour that his statements are condensed almost to the point of being unintelligible

Prof J S Huxley gives most interesting and well-written accounts of the courtship of animals and of sexual selection, and Sir J Arthur Thomson is equally successful in his treatment of parasitism Indeed, all the articles on what might best be described as natural history are excellent

In his article on marine biology, Prof J Johnstone has largely confined himself to a clear but very general account of the different zones and conditions of life in the sea The general reader is unfortunately left largely in ignorance of some of the recent advances in this subject, notably on the factors which control the abundance of the plankton and its variations throughout the year and in different regions

It remains only to mention the articles on special groups of the animal kingdom, three of which, on protozoa, sponges, and tunicata, have been examined The information therein contained is as concise and authoritative as the names of the re spective authors, Dr K Bělar, Dr G P Bidder, and Prof W Garstang, would lead us to expect They all, in greater or less measure, give an account of the functioning of the animals, as well as of their structure and systematics, and so bear witness to the slow but ever increasing accumulation of knowledge which, as Prof Watson states in his article on zoology, is gradually building up a science of comparative physiology, of which, it may safely be prophesied, the next edition of this great "Encyclopædia" will have much to say

Fuel Research in Great Britain.

THE Report of the Fuel Research Board for the year ending Mar 31, 1930 (London H M S O, 1930, 2s net), is an interesting document, because it seems to touch upon almost every technical problem of fuel in the British Isles

One of the original plans of the Board was the pro secution of a survey of the national coal resources The report shows that the recent establishment of a labora tory at the University of Leeds to study the West Yorkshire coalfield brings under survey areas producing 96 per cent of the coal raised, and the remaining 4 per cent can be handled by the existing organisation The value of this work will be increasingly recognised as time goes on One example is given in the report, namely, the publication of a hasty survey of Scottish coals made during the War, when the need arose to increase the production of furnace coke in Scotland, and it was found that the data had to be sought as an emergency measure

The report gives a survey of the position of low temperature carbonisation, leading to the conclusion that its true place in the carbonisation industries cannot yet be defined, although several processes are being worked on a considerable scale and making good solid fuel products The world prices for oil fuels have fallen so much recently as to make the economic posi tion of these processes worse Motor spirit is the most valuable by product, but the yields of this are usually small, and the most hopeful line appears to be the conversion of a larger portion of the tar into this product The tars themselves have such a character that they are largely inapplicable for the purposes to which tars are normally used In order to find a basis for exploitation, their chemistry is being studied at the Chemical Research Laboratory, Teddington Two methods are suggested for promoting the utilisation of tar. The first is the use of 'cracking', following the practice of the petroleum industry, but the tendency to form large quantities of coke and gas is unfavourable to the use of these tars as 'cracking stock' Alternatively, the tars may be hydrogenated under pressure, which may be regarded as a form of 'cracking' in which coke formation is prevented by the union of hydrogen with the fragments Very interest ing experiments in this direction are recorded By means of controlled hydrogenation, it has been possible to convert nearly the whole of a low temperature tar into motor spirit and neutral oil—the yields of the former working out at 16 gallons per ton of coal carbonised The Admiralty staff has also examined the possibility of using low temperature tar oil as fuel for steam raising and for Diesel engines, with encouraging results

The hydrogenation of coal and its products is obviously a subject of great potential importance nationally and to the coal industry Though much has been done by private interests, the amount of authentic published experience is not great The report describes the results of experiments—both static and continuous—on the hydrogenation of coal With the use of suitable catalysts, it is found that Continental experience can be repeated with British coals and satisfactory yields of oil obtained The character of the product is such that its after-treatment is difficult A modification of the process, in which the coal is treated with a rapid stream of preheated hydrogen, has shown that much better products can thus be obtained Indeed, it is stated that yields of motor spirit up to 120 130 gallons per ton of coal could be realised in a suitable plant Another interesting scientific observation is the possibility of converting non-coking coal into coking coal by partial hydrogenation

Much is hoped from the use of pulverised fuel as a

means of promoting the use of coal on board ship In land practice, coal-dust firing has been made possible by the use of large combustion chambers, but at sea this is impossible In essence, the problem is to bring air for combustion into contact with finely divided suspended particles—a problem in aerodynamics which is being systematically studied By attention to these requirements very high rates of heat release in small burners have been obtained, which should contribute to the solution of this problem

The staff of the Board has carried out laboratory work on the properties of coal, and also supported investigations by independent workers in the universities and elsewhere who have originated special techniques Thus Mr C A Seyler has been enabled to develop methods for studying polished surfaces of coal by reflected light His work has recently been published as a special report Mr Lomax is studying the distribution of spores in coal seams by examination of their sections This work, in association with that of the South Yorkshire Survey Laboratory, suggests the possibility of identifying and correlating seams by identification of the spores contained Interesting work in association with the Building Research Station is reported which should place the calculation of the heat requirements of buildings on a quantitative basis

In conclusion it may be said that the report comments on so many points that the reader can gather from it a very good idea of the status of British fuel problems in general H J HODSMAN

University and Educational Intelligence

CAMBRIDGE —In a report of the Council of the Senate on the future of mineralogy, petrology, and crystallography in the University it is recommended that, upon the retirement of Prof A Hutchinson from the professorship of mineralogy, the professorship of mineralogy be discontinued, and that there should be established in the University a professorship of mineralogy and petrology, assigned to the Faculty of Biology "A", and that a department of the same title be constituted, to include also the subject of crystallography

The Council of the Senate recommends that the Downing professorship of medicine be discontinued

Mr H H Brindley, University demonstrator in zoology, has been elected to a fellowship at St John's College

LEEDS —Courses of lectures on literary and scientific subjects will be given in the University during the Easter vacation, on April 15, 16, and 17, 1931 The lectures are intended primarily to meet the needs of those who find it difficult to keep in close touch with recent developments, and will also give opportunities for discussion Graduates of the University of Leeds will be admitted free, but for others a fee of £1 will be charged The science courses include lectures on the electronic theory of valency and on modern views on colloids, acids and bases, and the ionisation of electrolytes, and on the relationship between philosophy and various aspects of natural science Applications for admission to the course should be sent not later than Mar 21 to The Registrar, the University, Leeds, and should be accompanied by a remittance where payable

LONDON —Mr W B R King has been appointed as from Aug 1 next to the Yates Goldsmid chair of geology tenable at University College Since 1922 he has been fellow and Charles Kingsley lecturer at Magdalene College, Cambridge.

A University (part time) chair of medical psychology tenable at the London School of Hygiene and Tropical Medicine is to be instituted

ST ANDREWS —The Court has approved generally plans prepared by Mr J D Mills for a new building to provide accommodation for the departments of botany and geology at St Andrews, to be erected adjoining the group of buildings presently occupied by the Bute Medical School and the Bell Pettigrew Museum Plans have also been approved for the adaptation of Deanscourt, St Andrews, as an additional residence hall for men students

Dr W F Harper, hitherto assistant in anatomy, has been appointed a lecturer in regional anatomy in the University

THE American University Union (British Division), which has recently moved its London office from Russell Square to 1 Gordon Square, W C 1, announces, in a leaflet entitled "14 Points", the nature of the service it offers to American students and to British university graduates and others interested in American universities It facilitates meetings of British scholars with Americans, supplies, upon request from British societies, American college lecturers upon American subjects, and keeps a register of applicants for university posts in the United States Through the Institute of International Education (2 W 45th Street, New York), which publishes a monthly *Bulletin*, it undertakes arrangements for exchange professorships, visiting professorships, and exchange scholarships between British and American colleges It maintains personal touch, by visits, with each of the universities in Great Britain and Ireland, and tells them of the ways and aims of education in America It keeps on file the latest calendars of all representative American colleges, and answers questions about them, put by British educational authorities It co operates with the Continental Division of the Union (173 Boulevard St Germain, Paris) in the endeavour to help visiting scholars to acquaintanceships in any educational centre in Europe The director is W Connely

UNIVERSITY education in India is briefly discussed in the official pamphlet, "Education in India, 1927–1928", recently published (Calcutta Gov India Cent Pub Branch, 1 12 rupees) The rate of increase in the number of students in universities and arts and professional colleges (0 8 per cent of the total number of scholars in all kinds of institutions) is recorded as 0 84 per cent in twelve months, during which time the total of scholars of all kinds increased by 5 5 per cent Expenditure on university and collegiate education, which is 13 per cent of the total expenditure on education, increased at the rate of 7 per cent, as compared with an increase of 5 per cent in the total expenditure on education of all kinds The Indian Institute of Science, Bangalore, with its 100 students, accounts for 1 5 per cent of the expenditure on university and collegiate education Of four of the seventeen universities—Allahabad, Andhra, Lucknow, and Madras—it is recorded that they have adopted the principle of compulsory physical training for their students There are two religious denominational universities, the Aligarh Muslim and the Benares Hindu To each of them the United Provinces Government gave a recurring grant of 50,000 rupees to enable them to maintain departments of, respectively, Unani and Ayurvedic medicine In another direction the Benares Hindu University has broken away from the traditions of Indian universities by providing advanced courses which prepare for industrial life, and its diploma in engineering is recognised by employers as a guarantee of a sound training in mechanical and electrical engineering

Birthdays and Research Centres

Mar 8, 1855 —Prof K E VON GOEBEL, For Mem R S, professor of botany in the University and Director of the Botanical Gardens, Munich

At present I am engaged on the preparation of a work on "The Flowering Shoot" (anthocladia and inflorescences) to be published this year as the second supplement to the "Organographie den Pflanzen", third edition My main interest is the biology and taxonomy of leptosporangiate ferns

A critical revision of phylogeny, especially a comparison of the results of the phyto palæontological discoveries with the modern views on the relationships in the larger natural groups of plants, for example, in ferns, is a problem deserving of the closest study

Mar 9, 1862 —Sir SIDNEY F HARMER, K B E, F R S, formerly Director of the Natural History Departments of the British Museum

My principal work, at present, is the preparation of Part 3 of my *Report* on the Polyzoa collected by the *Siboga* in the Malay Archipelago

I continue to keep in touch with recent developments of the subantarctic whaling industry Whaling operations have increased in magnitude to an alarming extent, particularly since the season 1926–27, and principally as the result of the increased use of pelagic 'floating factories' which operate on the high seas These ships, which have already reached a size exceeding 20,000 tons, are capable of performing all manufacturing operations on board They are under no effective control, and there is reason to believe that in some cases a regrettable waste of valuable material is taking place The production of oil, in these localities, has risen from less than 800,000 barrels in 1925–26 to more than 1,600,000 barrels in 1928–29, and more than 2,500,000 barrels in 1929–30 (6 barrels = 1 ton) Naturalists acquainted with the results of earlier hunting in other areas are convinced that the whale population of subantarctic seas, the last refuge of the great whales, will be gravely reduced, in the near future, unless it is found possible to secure international agreement to the regulation of the industry, on satisfactory lines

Mar 13, 1873 —Dr CHARLES S MYERS, C B E, F R S, Director of the National Institute of Industrial Psychology

Much of the research work on which my staff and I have been engaged during the past ten years at the National Institute of Industrial Psychology has been fundamentally concerned with the mental differences between individuals Undoubtedly it suggests a problem of vast magnitude for future solution, namely, what are the *physiological* differences with which these *mental* differences are associated? What, for example, is the physiological significance of the discovery that, during the menstrual period, the mental efficiency of some women is distinctly greater, in others less, while in many it is not appreciably changed, compared with other times? What, again, is the physiological significance of similarly wide individual differences in efficiency which appear to result from ultra violet radiation? And what is the physiological significance of the striking differences in various mental characteristics revealed by mental tests?

Clearly, conjoint physiological and psychological research is essential to ascertain what *bodily* differences, say in metabolism, blood composition, or endocrine activity, are responsible for the *mental* differences disclosed by the Institute's research work

Societies and Academies

LONDON

Royal Society, Feb 26 —**J C Eccles and Sir Charles Sherrington** Studies on the flexor reflex (1) Latent period A method for measuring the latent period of the flexor reflex is described The values obtained for the central reflex time range from 2 7σ to 4 35σ, and are in general agreement with the values calculated by Jolly and by Forbes and Gregg The central reflex time is shortened when the stimulus applied to the afferent nerve is strengthened The temporal dispersion of many reflex discharges is shown to be due, not to the discharge of more than one impulse from motoneurones, but to variations in the latent periods of the single responses of different motoneurones The latent period of the response to a centripetal volley is greatly shortened if another volley precedes it by certain intervals This shortening occurs at the expense of the central reflex time It is concluded that all the time is saved in the reduction of the normal 'synaptic' delay by facilitation If that is so, the actual conduction time through the spinal cord must be less than 0 5σ On the assumption that the normal 'synaptic' delay is due to time taken for a succession of excitatory impulses (owing to their temporal dispersion) to build up a c e s of threshold intensity, all the observations are satisfactorily explained The experiments support the conclusions that in the flexor reflex, centripetal impulses are not transmitted straight through the spinal cord, but at certain points ('synapses') they are transformed into an enduring excitatory condition, c e s, which may in turn set up fresh nerve impulses—the reflex discharge —(2) The reflex response evoked by two centripetal volleys When the interval between two centripetal volleys is short, the reflex contraction evoked by the second volley is due largely to the discharge of motoneurones which fail to respond to either volley alone The response of these motoneurones is due to summation of the subliminal excitatory effects of each volley In addition to this facilitation at short intervals, a centripetal volley gives rise to a period of unresponsiveness of motoneurones Three types of unresponsiveness have been met with (a) Recovery complete in less than 16σ (b) Recovery complete in less than 50σ (c) Recovery not complete for more than 80σ From theoretical considerations, the duration of the relatively refractory period following an antidromic volley (10 5σ) is likely to be identical with the duration of the relatively refractory period of the reflex arc —**J C Eccles** Studies on the flexor reflex (3) The central effects produced by an antidromic volley When a single stimulus is applied to an intact motor nerve, a volley of impulses (called an antidromic volley) passes into the spinal cord through the ventral roots A single centripetal volley gives rise to c e s during a considerable period Persistence of the c e s set up by such a volley is due partly to the temporal dispersion of the incident excitatory impulses and partly to the c e s produced by any particular impulse itself enduring for some time In any motoneurone an antidromic impulse removes preformed c e s —**J C Eccles and Sir Charles Sherrington** (4) After-discharge A period of quiescence follows an antidromic volley set up during the after discharge of a reflex either by a single centripetal volley or by a repetitive series of centripetal volleys (confirming Denny Brown) It is concluded that preformed c e s of a motoneurone is removed by a reflex discharge and has to be built up again by delayed excitatory impulses before another discharge can occur —**J. C Eccles and Sir Charles Sherrington** (5) General

conclusions A brief statement with discussion of various views of the nature of central excitation in reflex activity —**A V Hill and J. L Parkinson** Heat and osmotic change in muscular contraction without lactic acid formation Frogs' muscles poisoned with iodo acetic acid, in which no lactic acid is formed, when stimulated to exhaustion in nitrogen gave total heat 0 367 cal per 1 gm and showed a rise of osmotic pressure This change of osmotic pressure cannot be explained in full without assuming either (*a*) that some chemical reaction, hitherto unrecognised, occurs in such poisoned muscles when stimulated, or (*b*) that phosphagen (and perhaps adenyl-pyrophosphoric acid) exist not as simple molecules in the resting muscle but in some combined form

Society of Public Analysts, Feb 4 —**L H Lampitt and J H Bushill** The solubility of milk powder—the moisture factor The authors stress the complicated nature of the changes which take place when spray-dried milk powder absorbs moisture The freezing of the fat, whereby it is made available for solution in organic fat solvents, is one indication of the changes taking place above the 'critical moisture content', a figure dependent upon the solids not fat —**S Marks and R S Morrell** (1) The determination of the hydroxyl content of organic compounds estimation of castor oil Peterson and West's modification of the method of Verley and Bolsing, in which the hydroxyl content is determined by treatment with acetic anhydride and pyridine, was found the most satisfactory method, and is particularly suitable for the estimation of castor oil —(2) The determination of the carboxyl and aldehyde content of organic compounds estimation of phenylhydrazine The most suitable method was found to be that of Ellis, in which the substance is treated with excess of phenylhydrazine, and the nitrogen evolved on treating the excess with Fehling's solution is collected and measured in a simple form of apparatus, an allowance being made for the benzene vapour —**A Van Raalte and J Straub** Food control in Holland Food control in Holland is based on legal standards arrived at usually by agreement between the directors of the control service and the large manufacturers Not only foods, but also other commercial products such as toilet articles, wallpaper, insecticides, etc, are subject to control There is a right of inspection of premises where food is manufactured or sold, and this, coupled with intensive sampling, has reduced to 6 7 per cent, the percentage of samples falling below the standard —**H R Ambler** The determination of small quantities of methane The hydrogen and carbon monoxide are oxidised by means of cupric oxide at about 500° C, the resulting carbon dioxide removed, and the methane determined by burning with oxygen in the presence of platinum wire at bright yellow heat, and measuring the carbon dioxide produced and the residual oxygen —**R Bhattacharya and T P Hilditch** The fatty acids and component glycerides of Indian ghee Cow ghee gives figures falling within the limits previously recorded for English and New Zealand butter fats, but buffalo ghee showed rather higher Reichert-Meissl and Kirschner values It also contained more butyric and stearic acids than cows' butter

Geological Society, Feb 11 —**W J Arkell**. The Upper Great Oolite, Bradford Beds, and Forest Marble of South Oxfordshire, and the succession of gastropod faunas in the Great Oolite In the first part of the paper the principal exposures in South Oxfordshire of the uppermost beds of the Great Oolite and the Forest Marbles are described, with especial reference to the palæontological horizons, and for the first time the fauna of the highest portion (or Block I.) of the Great Oolite is enumerated and discussed It is shown that this fauna is essentially a Great Oolite one Secondly, it is demonstrated that the renowned fossil bed of Islip contains nearly the whole of the highly characteristic assemblage of the Bradford Clay, of which it is held to be a true representative In the second part of the paper the gastropod beds of the Great Oolite are studied, and an attempt is made to disentangle the various species and genera —**A Heard and J F Jones** A new plant (*Thallomia*) showing structure, from the Downtonian Rocks of Llandovery, Carmarthenshire The structures of the peculiar fossil were revealed by mechanical and chemical methods of treatment Horizon Lower Downtonian, probably a few yards above the Upper Ludlow—Downtonian junction Locality Long west 3° 41′, lat north 51° 58′ 35″

PARIS

Academy of Sciences, Jan 5 —**Auguste Lumière and Mme A Dubois** The distribution of Koch's bacilli contained in milk, after separating the butter and casein Known amounts of tubercle bacillus were added to milk, the cream separated, and the casein separated from the butter milk in the usual way The resulting whey and the cream were free from bacilli which appear to be concentrated in the casein It is concluded that starting with tuberculous milk the maximum danger is in the cheese —**J Herbrand** The units of an algebraical body —**J Rey Pastor** A characteristic property of the varieties of Jordan —**H F Bohnenblust and E Hille** The absolute convergence of Dirichlet's series —**L Tchakaloff** The theorem of finite increments —**Georges Bouligand** Cavities arising in a heavy liquid —**G Ribaud and P Mohr** The determination of the melting point of platinum The method adopted was optical extrapolation, starting with the melting point of gold The melting point found was 1762° ± 2° C —**Mlle M Chenot** A new appearance of the high frequency discharge —**G Ferrié** Remarks on the preceding communication —**Armand de Gramont** Transmitted light in the case of so called total reflection If a light pencil is reflected from the long side of a right angle prism, under an angle of incidence greater than the limiting angle, some light diffuses through the back of the prism and shows a maximum in a definite direction The intensity of this maximum depends on the polish of the reflecting surface —**Jean Loiseleur and Léon Velluz** The preparation of cellulose membranes containing proteins The solubility of some proteins (gelatine, casein, egg albumen) in anhydrous organic acids allows the preparation of true solutions of mixtures of proteins and cellulose derivatives, and from these, by evaporation, membranes of varying permeability can be prepared —**P Pingault** The iron carbide and iron oxygen equilibrium —**L Hackspill, A P Rollet, and L Andrès** The action of boric acid upon the alkaline chlorides and nitrates In the presence of steam, boric acid easily displaces the acid of alkaline chlorides and nitrates —**M Lemarchands and C Tranchat** The purification of disodium phosphate —**A Travers and Avenet** The determination of thiocyanates in coke oven effluents The thiocyanate is precipitated as cuprous thiocyanate, this dissolved in ammonia, oxidised to cupric salt, and titrated with potassium permanganate —**Mme Ramart-Lucas and J Hoch** The absorption spectra of dibenzyl and its derivatives A band attributed by previous workers to dibenzyl has been found to be due to the presence of a trace of stilbene as impurity —**A Marin and P Fallot**. The distribution of the facies in the Spanish Rif and their special character —**Pierre Dangeard** A parasitic *Ectocarpus* causing tumours in *Laminaria flexicaulis*

(*Ectocarpus deformans*) —**Robert Weill** The genus *Pteroclava*, the systematic interpretation of the Pteronemidæ and the taxonomic value of the cnidome —**Georges Fontès and Lucien Thivolle** Tryptophane and histidine are anabolites The simultaneous injection of tryptophane and histidine into dogs, in equilibrium with a fixed food ration, results in rapid gains in weight, and these gains are maintained for some time —**L Septilici** The diagnosis of syphilis by spectroreaction —**C Levaditi and P Lépine** The preventive action of liposoluble bismuth in experimental syphilis of the chimpanzee

Jan 12 —**A Guldberg** The problem of the scheme of urns —**David Wolkowitsch** The geometrical properties of ellipses of inertia of a plane system — **J A Lappo-Danilevski** The analytical coefficient of the singularities of integrals of systems of linear differential equations with arbitrary rational co efficients —**N Mouskhelichvili** New method of reduction of the fundamental biharmonic problem to an equation of Fredholm —**J Dieudonné** The radius of univalence of polynomials —**O Nikodym** Linear and continued functionals —**J Dufay and R Gindre** The variable star d-Cygni The variations of luminosity suggest the mutual eclipses of two stars moving in circular orbits and give a curve of the type of β-Lyrae A detailed spectroscopic study is required to elucidate the physical nature of the system of d Cygni —**Jean Ullmo** The application of classical statistical conceptions to wave mechanics —**H Muraour and G Aunis** The variation of $\int p\, dt$ with density of the charge for different types of (explosive) powders —**Charles Marie and N Marinesco** The phenomena of adsorption and protection in complex colloidal media —**Augustin Boutaric and Jean Bouchard** The acceleration produced by light in the flocculation of colloidal solutions in fluorescent media Suspensions of gamboge and resin (in presence of eosin and fluorescein) and of arsenic sulphide sols (in presence of eosin, fluorescein, and erythrosin) were used It was generally found that flocculation is accelerated by light in the absence of the fluorescent substance the flocculation was not accelerated —**G Chaudron and A Girard** The formation of a ferromagnetic iron sesquioxide by the decomposition of van Bemmelen's hydrated sesquioxide —**V Agafonoff** The influence of impurities on some physical and crystallographic properties of hemimellitic acid Some anomalies in crystal form and optical properties were traced to the presence of impurities, one being calcium hemimellate —**V Gouzien** The geological structure of the peninsula of Crozen (Finistère) —**M Gignoux and E Raguin** The stratigraphy of the Trias of the Briançonnais zone —**Ch Poisson and J Delpeut** Magnetic observations at Tananarive —**L Mercier** The hypopleural bristles of *Orygma luctuosa* and the principle of the connexion of the organs —**Mme Lucie Randoin and Mlle Andrée Michaux** Variations in the proportions of chlorine and of water in striated muscle, liver, and kidneys in the course of acute experimental scurvy At the time of appearance of the characteristic symptoms of scurvy, the proportion of chlorine in the muscles shows marked increase, from 0 5 per thousand to twice or even three times this amount, and this is due essentially to the deficiency in vitamin C —**Raymond-Hamet** The cardiac antagonism of pilocarpine and tropine —**Jean Régnier and Guillaume Valette** The influence of the concentration of hydrogen ions on the fixation of cocaine by adsorption on the nerve fibres. The experiments described lend support to the hypothesis according to which increasing alkalinity increases the anæsthetic action of cocaine hydrochloride, not only by modifying the physico-chemical properties of the anæsthetic solution in a sense favouring fixation, but also by reinforcing the power of fixation of the nerve cell itself —**P Delanoë** The sensibility of the fox to the Moroccan spirochæte, *Sp hispanicum* var *marocanum* Young foxes are frequently infected, but as adult foxes can show a very complete acquired immunity, the fox, like the porcupine, must be regarded as a reservoir of the virus

Diary of Societies

FRIDAY, March 6

Royal Society of Medicine (Otology Section), at 10 30 A M —E D D Davis and others Discussion on Effects on Hearing after Fractured Base of the Skull Lessons Resulting Therefrom

Royal Sanitary Institute (at Guildhall, Swansea), at 3 —H R Tighe and others Discussion on The Rheumatic Child —Dr J M Morris E Morgan, and others Discussion on Housing

Royal Society of Medicine (Laryngology Section), at 5

Physical Society (at Imperial College of Science), at 5 —Dr G M B Dobson A Photoelectric Spectrophotometer for Measuring the Amount of Atmospheric Ozone —G F Tagg Practical Investigations of the Earth Resistivity Method of Geophysical Surveying —W E Pretty Displacement of Certain Lines in the Spectrum of Ionised Oxygen (O II, O III), Neon (Ne II), and Argon (A II)

Royal College of Surgeons of England, at 5 —Sir Arthur Keith Demonstration of the Nerve Supply of the Alimentary Tract and the Nature of Auerbach s Plexus

Society of Chemical Industry (Glasgow Section) (in Grosvenor Restaurant, Glasgow), at 6.45 —Annual Business Meeting

Society of Dyers and Colourists (jointly with Society of Chemical Industry) (at Engineers Club, Manchester), at 7 —S. M Neale The Action of Caustic Soda on Cellulose.

Institution of Electrical Engineers (Meter and Instrument Section), at 7 —J Urmston The Electrical High Pressure Testing of Cables and the Localisation of Faults.

Junior Institution of Engineers (at Science Museum), at 7 —The Historic Locomotives at the Museum

Institution of Mechanical Engineers (Informal Meeting), at 7 —A M Ling The Netherlands East India State Railways and Electrification (Lecture).

Royal Photographic Society of Great Britain (Pictorial Group), at 7 —Informal Meeting

Geologists' Association (in Architectural Theatre, University College), at 7 30.—Dr. C A. Matley The Deserts of California (Lecture).

Royal Institution of Great Britain, at 9 —Dr G M B Dobson Ozone in the Upper Atmosphere and its Relation to Meteorology

SATURDAY, March 7

Royal Society of Medicine (Anæsthetics Section) (at Bristol University), at 2.—Dr M Nierenstein, A. L Taylor, Prof R J Brocklehurst, A. L. Flemming, S. V Stock, Dr H. W Featherstone, Dr I W. Magill Symposium on the Barbiturates in Anæsthesia

Royal Institution of Great Britain, at 3 —Lord Rutherford : Recent Researches on the Alpha Rays (1).

Institute of British Foundrymen (Lancashire Branch) (at College of Technology, Manchester), at 4 —H G Scott The Blast Furnace, its Limitations and its Relation to the Cupola

Institute of British Foundrymen (Scottish Branch) (at Royal Technical College, Glasgow), at 4 —M Russell Pattern making and its Relation to Design and Foundry Practice

Institute of British Foundrymen (West Riding Branch) (at Technical College, Bradford), at 6 30 —H W Swift Commercial Tests for Cast Iron

MONDAY, March 9

Cambridge Philosophical Society (in Cavendish Laboratory), at 4 30 —Dr E D Adrian Electric Charges in Nervous Tissues — *Papers to be communicated by title only* —W N Bailey Some Series and Integrals Involving Associated Legendre Functions —J A Todd The Groups of Symmetries of the Regular Polytopes —H S M Coxeter The Densities of the Regular Polytopes —L Roth Some Properties of Line Congruences —W H Ingram Note on the Operability of Synchronous Motor at the End of a Transmission Line —R. H Fowler A Note on Ferromagnetism —F W G White A Theoretical Discussion of the Electrical Properties of the Soil —Dr T M Harris *Rhætic Floras* —Prof L Hogben *Some Biological Aspects of the* Population Problem —Dr V B Wigglesworth The Respiration of Insects

Royal Society of Medicine (United Services Section), at 5 —Squadron Leader H L Burton and others Discussion on Minor Head Injuries

Royal College of Surgeons of England, at 5 —C E Shattock Demonstration of Specimens illustrating Diseases of the Colon and Rectum

Institution of Automobile Engineers (Birmingham Centre) (at Queen s Hotel Birmingham), at 7 —J E Arrowsmith *Pressings for Automobiles*

Institution of Electrical Engineers (North Eastern Centre) (at Armstrong College Newcastle upon Tyne) at 7 —J W Rissik and H Rissik Heavy Duty Rectifiers and their Application to Traction Sub stations

Institute of Metals (Scottish Section) (at 39 Elmbank Crescent, Glasgow) at 7 30 —Annual General Meeting

Royal Society of Arts at 8 —A. G D West The Recording and Reproducing of Sound (Cantor Lectures) (1).

Royal Geographical Society, at 8 —Major R. W G Hingston Proposals for British National Parks in Africa

Chartered Surveyors Institution at 8 —G Lovegrove The Amendment of the London Building Acts

Eugenics Society (at 20 Grosvenor Gardens S W 1), at 8 15 —Study Circle.

TUESDAY, March 10

Royal College of Physicians of London, at 5 —Dr M Critchley The Neurology of Old Age (Goulstonian Lectures) (1).

Royal Institution of Great Britain, at 5 15 —Dr C D Darlington The Cytological Theory of Heredity and Variation (1)

Institution of Civil Engineers, at 6

Institute of Marine Engineers, at 6.—G S Baker The Efficiency and Steering Effect of Inward and Outward Turning Screws

Institute of Metals (Swansea Section) (at Y M C A., Swansea), at 6 15 —Prof F C Thompson Some Researches on the Wire Drawing Process

Eugenics Society (at 20 Grosvenor Gardens, S W 1), at 6 30 and 8 30 — Study Circle

Society of Chemical Industry (Birmingham and Midland Section) (at Chamber of Commerce, Birmingham), at 6 45 - E C F King Rust proofing of Iron and Steel

Institution of Electrical Engineers (North Western Centre) (at Engineers Club, Manchester) at 7 —P J Ryle Two Transmission Line Problems Suspension Insulators for Industrial Areas in Great Britain Conductor Vibration

Royal Photographic Society of Great Britain at 7 —Annual General Meeting

Institution of Heating and Ventilating Engineers (Associate Members and Graduates Section) (Manchester and District Branch) (at Milton Hall, Manchester), at 7 —H R. Hiscott Malleable Fittings.

Institution of Heating and Ventilating Engineers (Associate Members and Graduates Section) (at Borough Polytechnic), at 7 —H L. Egerton Domestic Hot Water Supply

Institution of Electrical Engineers (Scottish Centre) (at 39 Elmbank Crescent, Glasgow) at 7 30 —E T Norris and F W Taylor High Voltage Testing Equipments —B L. Goodlet, F S. Edwards, and F R Perry Dielectric Phenomena at High Voltages

Institute of Metals (North East Coast Section) (Annual General Meeting) (at Armstrong College, Newcastle upon Tyne), at 7 30 —R D Burn The Longmaid-Henderson Process *for the Extraction of* Copper

Quekett Microscopical Club (at 11 Chandos Street, W 1), at 7 30.— C D Soar British Acarina

WEDNESDAY, March 11

Institution of Engineering Inspection (at Royal Society of Arts), at 5 30 —Lt Col J T C Moore Brabazon Motor Racing and its Influence on Technical Design

Institute of Fuel (at Chemical Society), at 6.—J Roberts Formation of Coke.

North East Coast Institution of Engineers and Shipbuilders (Graduate Section) (at Bolbec Hall, Newcastle-upon Tyne), at 7 15.— R Harding The Automatic *Stabilisation of Ships.*

Royal Society of Arts, at 8.—A. J Davis Architectural Decoration

Eugenics Society (at Linnean Society), at 8.30

Television Society (at University College).

THURSDAY, MARCH 12.

ROYAL SOCIETY, at 4.30.—E. W. Fish: On the Reaction of the Dental Pulp to Peripheral Injury of the Dentine.—E. B. R. Prideaux: The Combination Curves, Hydrogen Ion Regulating Power and Dissociation Constants of Gelatin.—R. Snow: Experiments on Growth and Inhibition.

LONDON MATHEMATICAL SOCIETY (at Royal Astronomical Society), at 5.—W. G. Bickley: Some Integrals Involving the Jacobian Zeta Function, and the Sums of Certain q Series.—H. S. M. Coxeter: Groups whose Fundamental Regions are Simplexes.—C. Fox: An Integral Transform and Some Applications.—S. Goldstein: A Note on Certain Approximate Solutions of Linear Differential Equations of the Second Order.—F. H. Murray: Asymptotic Dipole Expansions for Small Horizontal Angles.—R. Wilson: Eliminants of Characteristic Equations.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, at 5.—Dr. M. Critchley: The Neurology of Old Age (Goulstonian Lectures) (2).

ROYAL INSTITUTION OF GREAT BRITAIN, at 5.15.—Prof. J. B. S. Haldane: Respiration (4).

INSTITUTION OF ELECTRICAL ENGINEERS, at 6.—J. W. Rissik and H. Rissik: Heavy Duty Rectifiers and their Application to Traction Substations.

ROYAL AERONAUTICAL SOCIETY (jointly with Institute of Transport) (at Royal Society of Arts), at 6.30.—Capt. O. Florman: Night Air Mails.

INSTITUTE OF MARINE ENGINEERS (Junior Section), at 7.—H. R. Tyrrell: Experiences of a Junior Engineer on his First Voyage.

SOCIETY OF CHEMICAL INDUSTRY (Nottingham Section) (at University College, Nottingham), at 7.30.—J. Kwantes: Chemistry in Beet Sugar Manufacture.

OPTICAL SOCIETY (at Imperial College of Science), at 7.30.

INSTITUTION OF WELDING ENGINEERS (at Institution of Mechanical Engineers), at 7.45.—Dr. A. B. Everest: Cast Iron To-day.

ROYAL SOCIETY OF MEDICINE (Neurology Section), at 8.30.—O. G. Morgan and Dr. C. P. Symonds: Unilateral Ophthalmoplegia with Absent Tendon Jerks.—Dr. R. Brain: Grasp Reflex in the Foot.—Cinematographic Demonstrations.—Dr. S. Barnes: A Case of Unusual Dissociation of Voluntary Eye Movement.—Dr. H. Cohen: Technique and Results of Encephalography and Ventriculography.

FRIDAY, MARCH 13.

BIOCHEMICAL SOCIETY (Annual General Meeting) (at University College), at 3.—Prof. C. Lovatt Evans, Chiao Tsai and F. G. Young: A Note on the Estimation of Liver Glycogen.—R. A. McCance and H. L. Shipp: The Colorimetric Determination of Sodium.—E. Stedman and Ellen Stedman: Studies on the Relationship between Chemical Constitution and Physiological Action. Part III. The Inhibitory Action of Certain Synthetic Urethanes on the Activity of Liver Esterase.—B. C. J. Knight: An Electrolytic Method for Poising the Oxidation-reduction Potential of Culture Media.—G. F. Marrian: Observations on the Physiological Potency of Crystalline Tri-hydroxy Œstrin.—Prof. T. P. Hilditch and J. J. Sleightholme: The Glyceride Structure of Butter Fats.—H. R. Ing and R. N. Kekwick: A Note on Acyl Derivatives of Creatine and Creatinine.—I. S. MacLean and M. S. B. Pearce: Oxidations of Oleic Acid *in vitro* and their Bearing on the Biological Oxidation of Oleic Acid.—C. Rimington and A. M. Stewart: A Pigment from the Suint (Sweat Fraction) of Raw Sheep's Wool.

ROYAL SOCIETY OF ARTS (Indian Meeting), at 4.30.—Dr. H. H. Mann: The Tea Industry of India in its Scientific Aspects.

ROYAL ASTRONOMICAL SOCIETY, at 5.—Sir A. S. Eddington: A Theorem concerning Incomplete Polytropes.—J. Young: Occultations of Stars by the Moon observed at Birmingham University during 1930.—T. Matukuma: Relativity Effect in the Problem of Latitude Variation.—J. Dufay: Effect of Atmospheric Absorption in Stellar Spectrophotometry.—J. H. Hindle: A New Test for Cassegrain and Gregorian Secondary Mirrors.—V. V. Narlikar: The Significance of Bode's Law in Relation to Satellite Systems.—L. H. Thomas: The Slow Contraction and Expansion of a Fluid Sphere. II. Stability.—S. Chandrasekhar: The Dissociation Formula According to the Relativistic Statistics.—O. S. Beals: Wave Lengths of Oxygen and Nitrogen Lines in the Stellar Region.—Royal Observatory, Greenwich: Observations of Solar Flocculi made with the Spectrohelioscope during 1930.—Dr. H. H. Plaskett: The Formation of the Magnesium b Lines in the Solar Atmosphere.—B. Strömgren: The Possible Solutions of the "Equations of Fit" on the Standard Model.—T. G. Cowling: Note on the Fitting of Polytrope Models in the Theory of Stellar Structure.—S. Chandrasekhar: The Highly Collapsed Configurations of a Stellar Mass.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Sir Arthur Keith: Demonstration of Specimens illustrating the Anatomy, Physiology, and Pathology of the Œsophagus.

MALACOLOGICAL SOCIETY OF LONDON (at Linnean Society), at 6.

NORTH EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (at Mining Institute, Newcastle-upon-Tyne), at 6.—S. F. Dorey: Some Factors Influencing the Sizes of Crankshafts for Double Acting Diesel Engines.

INSTITUTION OF ELECTRICAL ENGINEERS (London Students' Section), at 6.15.—C. J. F. Tweed: Aspects of the Transmission and Reception of Still Pictures.

INSTITUTE OF FUEL (North Western Section) (at Engineers' Club, Manchester), at 7.—Dr. G. E. K. Blythe: The Industrial Application of Pulverised Fuel.

OIL AND COLOUR CHEMISTS' ASSOCIATION (Manchester Section) (at Milton Hall, Manchester), at 7.—Dr. F. A. Mason: Recent Lines of Advance in Lake and Pigment Chemistry.

JUNIOR INSTITUTION OF ENGINEERS, at 7.30.—L. Clegg: Phenol Formaldehyde Moulding Compositions: Manufacture and Use.

SOCIETY OF CHEMICAL INDUSTRY (Chemical Engineering Group) (at Chemical Society), at 8.—W. J. Rees: The Manufacture of Lime.

ROYAL INSTITUTION OF GREAT BRITAIN, at 9.—J. C. Squire: Parody.

SATURDAY, MARCH 14.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Lord Rutherford: Recent Researches on the Alpha Rays (2).

ANNUAL MEETING.

MARCH 11 AND 12.

INSTITUTE OF METALS (Annual General Meeting) (at Institution of Mechanical Engineers), at 10 A.M., etc.

Papers to be submitted:

S. L. Archbutt and W. E. Prytherch: Investigation of the Effect of Impurities on Copper. Part VII. The Effect of Antimony. Part VIII. The Combined Effect of Antimony and Arsenic.

L. J. Brice: Some Properties of Silicon-Aluminium Bronzes.

Capt. W. F. Collins: The Corrosion of Early Chinese Bronzes.

Dr. P. J. Durrant: The Constitution of the Cadmium Rich Alloys of the System Cadmium-Silver.

Dr. C. F. Elam: An Investigation of the Microstructures of Fourteen Silver Greek Coins (500-300 B.C.) and some Forgeries.

O. W. Ellis: The Rolling of Alloys of Copper and Phosphorus containing up to 5 per cent of Phosphorus.

Dr. H. J. Gough and H. L. Cox: The Mode of Deformation of a Single Crystal of Silver.

J. D. Grogan and D. Clayton: Dimensional Stability of Heat-treated Aluminium Alloys.

Prof. D. Hanson: The Flow of Aluminium at Elevated Temperatures.

T. P. Hoar and R. K. Rowntree: Note on the Silver Rich Aluminium-Silver Alloys above 600° C.

Dr. C. H. M. Jenkins: Some Properties of Metallic Cadmium.

Dr. K. L. Meissner: The Effect of Artificial Ageing upon the Resistance of Super Duralumin to Corrosion by Sea Water.

C. E. Pearson and Dr. J. A. Smythe: The Influence of Pressure and Temperature on the Extrusion of Metals.

Dr. D. Stockdale: The Solid Solutions of the Copper-Silver System.

PUBLIC LECTURES.

FRIDAY, MARCH 6.

CHEMICAL SOCIETY (at Institution of Mechanical Engineers), at 5.30.—Prof. H. Wieland: Studies on Biological Oxidation (Pedler Lecture).

SATURDAY, MARCH 7.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—Miss I. D. Thornley: Mediæval Maps and Travellers' Tales.

MONDAY, MARCH 9.

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE (Public Health Division), at 2.—T. D. Young: Meat Inspection.—At 5.—J. C. Dawes: Public Abattoirs: Lay-out, General Arrangement, etc.

LONDON SCHOOL OF ECONOMICS, at 5.—Rev. Edwin W. Smith: The Application of Social Anthropology to Practical Affairs. (Succeeding Lectures on Mar. 10 and 11.)

TUESDAY, MARCH 10.

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL, at 5.15.—Dr. E. W. Hurst: Dessеminated Encephalomyelitis following the Exanthemata (Vaccination, etc.).

KING'S COLLEGE, LONDON, at 5.30.—Prof. G. Dawes Hicks: Sense Perception and Physical Thing.

WEDNESDAY, MARCH 11.

BRITISH MEDICAL ASSOCIATION (Tavistock Square), at 5.15.—Dame Louise McIlroy: Maternal Mortality (Chadwick Lecture).

ROYAL ANTHROPOLOGICAL INSTITUTE (at Portland Hall, Great Portland Street, W.1), at 5.30.—E. Torday: The Things that matter to the West African.

KING'S COLLEGE, LONDON, at 5.30.—Prof. E. G. R. Taylor: The Great Age of Discovery: The Northern Passages.

THURSDAY, MARCH 12.

UNIVERSITY COLLEGE, at 5.30.—Dr. A. M. Bassani: Pompei (in Italian).

TEXTILE INSTITUTE (London Section) (at Barrett Street Trade School, W.1), at 7.—Sir Francis Goodenough: Salesmanship.

FRIDAY, MARCH 13.

BRITISH MEDICAL ASSOCIATION (Tavistock Square), at 3.—Prof. E. Mellanby: Diet and Health (Sir Charles Hastings Lecture).

SATURDAY, MARCH 14.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—D. Martin Roberts: London in the Augustan Age.

CONFERENCE.

FRIDAY, MARCH 6.

INSTITUTION OF CHEMICAL ENGINEERS (Annual Corporate Meeting).

Friday, Mar. 6 (at Hotel Victoria), at 11 A.M.—Presentation of the Osborne Reynolds Medal, the Moulton Medal, and the Junior Moulton Medal.

At 11.45 A.M.—The President and others: Discussion on The Education and Training of the Chemical Engineer.

At 2.15.—Dr. D. M. Newitt: The Flow of Gases at High Pressure through Metal Pipes.

CONVERSAZIONE AND EXHIBITION.

SATURDAY, MARCH 7.

GILBERT WHITE FELLOWSHIP (at 6 Queen Square, W.C.1), at 3.

SATURDAY, MARCH 14, 1931.

Industry and Scientific Research.

THE close relation between the dyestuffs industry and general organic research emphasised in the course of recent Parliamentary debates on the Dyestuffs (Import Regulation) Act was not controverted by those who considered that the Act should be allowed to lapse On the other hand, doubts as to whether Imperial Chemical Industries, Ltd, by which the major proportion of dyestuffs research in Great Britain has been conducted, was doing so much for research as might be expected, and a suggestion that such research was being or might be curtailed, were alleged by certain members as reasons for not voting for a measure which they would otherwise have supported The report of the Dyestuffs Development Committee, indeed, shows that there has been a slight decrease in the number of research workers employed in the dyestuffs industry between 1920 and 1928 This difference, however, as Major A G Church has pointed out, is largely due to the attraction of such research workers into other industries Apart from this, the figures given in the report are too early to record the full effect of the extension of research activity in this field which has resulted from and only become possible through the pooling of resources following the formation of Imperial Chemical Industries, Ltd

The relation between industry and research is extremely complicated, and there are certain aspects which were by no means covered in the recent debates and discussions It must be conceded that industrial research inevitably has an economic trend, which may at times impose limitations There is a certain amount of justification for making research obligatory when State support is given in any form On the other hand, the prosperity of the dyestuffs industry and the organic chemical industry depends essentially upon continuous and wisely directed research Any relaxation of effort in that direction would speedily result in decay It is open to debate whether any stipulation regarding research could be made without involving machinery for control which would be a serious hindrance to scientific management

The problems raised are not peculiar to Great Britain Prof R Willstatter has recently directed attention to the changed relations between the universities and chemical industry in Germany (*Chem Zeit*, **54**, 793, 1930, **55**, 1, 1931), and views with serious concern the increasing difficulty with which the newly qualified chemists are absorbed into industry and their insecurity of tenure Such conditions he regards as dangerous to the scientific

position of Germany, which cannot be maintained if students of ability are no longer freely attracted by scientific studies and careers

The opinion has been expressed that the world is suffering from over-production of chemists and of research, in common with over-production of all kinds This view is probably encouraged by the common impression that there are now no striking advances to be made in the field of organic chemistry, pure or applied Its main principles have in general been discovered, and the research chemist, whether in industry or in scientific laboratories, is now occupied with the intensive study of relatively small parts of the field

While the apparent orderliness of the immense edifice developed from Kekulé's theory undoubtedly strengthens the impression that chemistry is a static science, such a view is fundamentally false If propounded twenty or thirty years ago, since when the main structure of theoretical organic chemistry has remained essentially unchanged, this view would have been confounded by subsequent discoveries and advances in almost every branch of organic chemistry Well within these three decades we have seen the development of the rayon industry, the synthetic resins industry, the cellulose lacquer industry, oil-cracking, and low temperature carbonisation Immense developments have been recorded in the production of insecticides and synthetic drugs and in the vulcanisation of rubber The technical production of indigo essentially dates from the Deutschen Gold- und Silberscheideanstalt or Roessler sodamide fusion patent of 1901, the Sandmeyer process from thiocarbanilide being still more recent Moreover, within this period there is scarcely one of the older fields which can be described as exhausted or failing to produce fresh wealth The oldest section of the dyestuffs field, the triphenylmethane or aniline colours, formerly regarded as comparatively fugitive, was found in 1915 to be capable of yielding with phosphotungstic acid a series of lake or pigment colours of surpassing light fastness, whilst the azo section is still providing new dyestuffs to overcome the dyeing difficulties presented by the new rayon fibres

Although many of the branches of organic chemical industry have sprung from the discoveries, often fortuitous, made in scientific laboratories—as, for example, Perkin's mauve, Griess's azo dyes, Baeyer's phthaleins and synthetic indigo, Knorr's antipyrine, Ehrlich's salvarsan, the nitrocellulose silk of Count Chardonnet, the viscose of Cross—the significance of such discoveries was frequently unrealised at the time either by scientific workers or industry This alone should make us cautious in advocating any restriction of research There are too many problems in our national and industrial life urgently demanding scientific solutions for such a policy to be either timely or wise It is almost impossible to predict just where the next important advance will be made, or, in reviewing the results of a year's investigations, to single out the one discovery by which posterity will mark the year

The influence of industry on scientific research is, however, fully as important as that of scientific research on industry Even in the field of technique it is impossible to assess the contributions of either on a cash basis The greater resources of the industrial research laboratory and its improved and frequently more advanced technique are continually reacting on scientific laboratories The range of reaction conditions open to the organic chemist has enormously expanded in the last decade, and processes can now be effected in extremely high vacuum or under pressures of several thousand atmospheres and at temperatures ranging from the neighbourhood of absolute zero to those of the electric furnace, whilst the activators or catalysts available range from the new organic catalysts, bordering on biochemistry, over almost the whole field of inorganic chemistry

Nor is it only refinements of technique that are continually changing the conditions of scientific and industrial research Almost every year sees fresh compounds, formerly curiosities and accessible only by tedious and costly laboratory processes, produced on the commercial scale at a price which allows their use in industry or in scientific laboratories as the raw material of further researches The papers published in the journal of any chemical society reveal the way in which the scope of scientific research has been enlarged and influenced by industrial advances The utilisation of waste materials, the delicate balance between by product and main-product, the fall or rise in price of basic materials like sulphuric acid, methyl alcohol, glycerol, which alone may result in new routes for existing products—the war-time shortage of sulphuric acid, for example, led to the development of alternative processes for phenols and amines which have not been entirely replaced by the earlier methods—these are factors which continually emphasise the dynamic character of industrial research and frequently have far reaching effects on scientific research

If, however, the increasing complexity of the field of organic chemistry makes restriction of re

search inconceivable, the demands made on leadership are increasingly severe It was never easier than to-day for research ability to be wasted in an attack on unprofitable problems Scientific progress has almost invariably come from the ideas and work of a talented few, and depends as much upon the quality and personality of the investigator as upon his technique The most serious problem is the production of research leaders of the requisite imagination, foresight, and enthusiasm to direct wisely the team work which modern industrial research demands Any circumstance, whether of rates of pay, status, or insecurity of tenure, which hinders the recruitment for industrial research of potential leaders of the requisite calibre is a national and not merely an industrial danger There is little doubt that if the concentration of professional opportunities within at most one or two firms, as in Germany, does affect adversely the position and prospects of chemists, industry will quickly suffer from the reaction

The distinction between scientific and industrial research to-day is not easy to define Their relationship is dynamic and so intimate that circumstances which injure or cramp one react likewise on the other neither can advance while the other is starved, and on this fact Prof Willstatter based his plea for more generous assistance for the German universities from chemical industry Such assistance is now being given more freely in Great Britain, and the closer relationship between the universities and industry are undoubtedly to their common advantage

It is easy, however, to overstress from either side the economic aspects of the relation between industry and scientific research If there are ways in which scientific research cannot compete with industry, there are still inestimable services which scientific research can render to the nation as well as to industry Scientific research, in its freedom from the economic motive, can do much to counteract that tendency in industry for the good to be the enemy of the best, and to secure our advance to the best of all possible solutions Scientific research, in the widening fields opened to it by industrial developments, can use its resources to explore the byways, the economically unattractive fields from which will come in the future, as they have so often in the past, the fundamental and epoch making discoveries On such workers, too, in their quest of truth for truth's sake, must ever fall the responsibility of kindling and rekindling that enthusiasm and devotion to which alone Nature yields her most precious secrets

Faraday's Worth in Wisdom

A Tribute to Michael Faraday By Rollo Appleyard Pp xiii + 204 + 21 plates (London Constable and Co , Ltd , 1931) 7*s* 6*d* net

"A magnet hung in a hardware shop,
(said it) If I can wheedle
A knife or a needle,
Why not a Silver Churn ?"

HOW this was to be done was shown at the Royal Institution, ages before Gilbert stated the fable of the magnet and the silver churn and knowing no physics gave it the wrong 'moral'

The industrial value of Faraday s discoveries has long been patent, throughout the civilised world little heed has yet been given to the example he set and to the spiritual doctrine he professed Perhaps, in near days to come, hastening as we now are the exhaustion of natural resources, through disproportionate use of machinery and greed of gold, his spiritual legacy may be of more value to us in overcoming and directing the crude, untamed human nature within us, which our modern advance in knowledge serves but to cover with a thin veneer In celebrating in September, this year, the centenary of his greatest discovery, we shall do well to consider his moral worth and teaching at least as fully as his contributions to knowledge Something we must do to save the world from government by *Alfalfa Bills* and Oklahoma waste of oil (*Times*, Feb 17, 18)

The appearance of Mr Appleyard's book is opportune He has not only sought out particulars of Faraday s forebears in their north country homes and of Faraday's father at his Newington, South London, forge but has also delved into Royal Institution archives and elsewhere thus garnering not a few items of interest which are welcome additions to the story of the immortal scientific magician He also has an interesting chapter touching on Clerk Maxwell's work in connexion with Faraday, as the mathematical exponent of its meaning The book is one to ponder well Various arresting moments in the philosopher's life are dealt with in a way that will appeal to all who can appreciate the charm of Mr Appleyard's style and his sympathetic attitude towards his subject We can picture him, upon an Athenæum sofa, browsing in search of inspiration We can ourselves browse with delight upon the lawn which he has consequently laid out for us as sward it would scarcely appeal to the Sutton firm , the herbage is more that of a Swiss upland pasture, in which gentian blue is mixed with anemone

yellow, set off with multi-coloured pansies and occasional red silene.

With such an example before them, the Arnold Bennetts need gibe no more at the scientific worker's literary ineptitude but take lessons from the book, how they may put real substance into their lines: it is seducing, though no seductions are pictured in the Saga; the young may read it with advantage, not merely with safety.

Yet when it is read—when the whole of the literature relating to the man, including his own works, is studied—we remain unable to account for the miracle he himself was. Seemingly, a magnetic personality was beaten into him by his father's hammerings. Maybe, he had his being in the unit charge of electricity which he was the first to divine: nearer we can scarcely get. In the East, he would long since have passed into tradition as a god. In his own country his name has yet to figure in the history books. Definitely a prototype, to be idealised as the truly scientific, all but faultless experimentalist and natural philosopher, the early stages of his mental development remain unfathomable. He was not a bookbinder's apprentice for nothing. He early became a reader of informative books; his style was formed, the habit of thinking for himself and his experimental outlook established, prior to his coming under Davy's inspiration—for Davy also was an inspired worker. Under and from him, he must have learnt much: it is strange that we know nothing of their intercourse. A man who could do what Davy did at so early a period, while on travel, with the simplest appliances, probably in his bedroom—who could work out the chemistry of iodine and establish diamond as carbon while visiting a foreign Court—must have had a magnetic personality and influence. The lines of force already ruled in Faraday's character must have been wondrously cut through and drawn out by such example. Still, in those years, he was but finding himself and overcoming his innate humility; he developed late, we know. This perhaps is why he passed no remark upon his master's work. On the other hand, we should be mindful of the advantage he enjoyed—one that none of us can enjoy to-day—in having an all but virgin field. Not because this gave boundless opportunity for discovery but because he was able to work without prejudice. Can a mind possibly grow up to-day so clean as Faraday's was? I doubt it. The student to-day rides in upon the last wave of fashion: so narrow is our human intelligence that he cannot thereafter rid himself of first impressions. We have only to think of the way in which the fear of the devil has been put into man's mind by priesthoods. The teachers of natural science are but a priesthood to-day, too often teaching faiths in misinterpretation of facts. Faraday was all but free from such priestly influence. We have yet to appreciate the perils of positive education dominated by examinations.

Faraday himself preached the most perfect sermon that has ever been preached, before Prince Albert, the Prince Consort, in 1854. Let us hope that this will be put into the hands of, at least, every visitor to the exhibition that will be held in September next at the Albert Hall. He laid down clear rules for mental education. The doctrine set out by Herbert Spencer, Huxley and others is already far better stated in this lecture—better because Faraday was both experimentalist and seer whilst they were doctrinaire teachers, Spencer especially.

In only one particular was Faraday subject to the restrictive influence of education and convention—that of religion. He was a strict Glasite (a Sandemanian). He kept his Sunday mind rigidly apart from his week-day mind, a fact sufficiently remarkable to deserve close psychological study. Since his day, not a few scientific workers of distinction have maintained a like attitude. Within us is an inherited power which not only limits our freedom of thought but also tends to direct us. Three words, said Faraday, express the great deficiency in the exercise of the mental powers: *deficiency of judgment*. The inability remains with us to day. It seems improbable that more than the few will ever learn to form *proportionate judgments*. Some of us have hoped that the faculty would be the outcome of early training in understanding and the use of knowledge: that it has not been so hitherto, let us hope, is because we have not yet learnt sufficiently to appreciate the force of Faraday's teaching and example as to apply it properly.

That Faraday was free from bias and prejudice in his experimental work is clear from his attitude towards spiritualism. He made table-turning the subject of close rational study and inquiry—with negative results. The conclusion of his letter on the subject is striking:

"I think the system of education that could leave the mental condition of the public body in the state in which this subject has found it, must have been greatly deficient in some very important principle."

We do not seem to have advanced very far in

the interval of nearly eighty years, notwithstanding all our education.

Faraday is remarkable in comparison with Ruskin, a man of eminently artistic temperament, yet highly scientific in his manner of work, a more than competent geologist Owing to his mother's commanding influence, Ruskin was a militant churchman It is clear that, as he grew older, he modified his views in no slight degree in late life, he even confessed that, were he to begin again, he might have shed his orthodoxy—it was only too late to begin Faraday and Ruskin moved in worlds apart—yet they had much in common To them we may add a third great influence in Victorian days—Carlyle. It may well be that such men are no longer possible—that the influence of 'combines' and of so-called 'rationalisation' in industry is to crush out the element of individuality to eliminate the element upon which the moral stability of the world specially depends Science to day is not cultivated to moral purpose so much as to gain some private end an we be not careful, future generations may have to record that, like the dog in the poem, it 'went mad and bit the man'

To be orthodox, let me say the book has a perfect index and wonderful pictures—the Royal Institution looks a mile long, as it ought to be !

HENRY E ARMSTRONG

Systematic Zoology.

Handbuch der Zoologie eine Naturgeschichte der Stämme des Tierreiches Gegründet von Prof Dr Willy Kukenthal Herausgegeben von Dr Thilo Krumbach Band 2 *Vermes Amera, Vermes Polymera, Echiurida, Sipunculida, Pria pulida* (1) Lieferung 6 (Teil 4 und Teil 5) Pp 147-242 + 64 17 gold marks (2) Lieferung 7, Teil 2 Pp 129-256 14 gold marks (3) Lieferung 8, Teil 4 Pp 243-402 18 gold marks (4) Lieferung 9, Teil 1 Pp 113-192 10 gold marks (5) Lieferung 10, Teil 4 Pp 403 482 10 gold marks (6) Band 4 *Progoneata, Chilopoda, Insecta* Lieferung 8 Pp 801-892 12 gold marks (7) Band 7 *Sauropsida, Allgemeines, Reptilia, Aves* Halfte 2, Lieferung 5 Pp 433-544 12 gold marks (Berlin und Leipzig Walter de Gruyter und Co, 1929)

SINCE our last notice of this valuable work, seven new parts have been issued The editor and the publishers are to be commended for their sustained zeal and for the manner in which text and illustrations are being produced. The parts before us are planned on the same lines as their predecessors, already noticed in these columns

(1) In this part three small but interesting groups of animals are considered Dr Remane, who has in recent years contributed a good deal to our knowledge of the Gastrotricha, is responsible for the account of this group and of the Kinorhyncha, and Prof Cori for that of the Kamptozoa (that is, the Polyzoa Entoprocta) All three chapters are noteworthy for the excellence of both text and figures, and they fully supply the needs of the advanced student Prof Cori has worked over the anatomy and histology of *Pedicellina* and has prepared more than forty original drawings, chiefly of this genus *Arthropodaria benedeni* occurs, as is stated, at Ostend, Prof Cori has omitted the record of this species from Hull, and of *Barentsia gracilis* from the Isle of Man

(2) Prof Fuhrmann, the author of the chapters on Trematoda, has written this account of the class Cestoidea, which includes the subclasses Cestodaria (with two orders Amphilinidea and Gyrocotylidea) and Cestoda In discussing the morphology of Gyrocotyle and its relative *Gyrocotyloides* (a new genus) the author advances good reasons for regarding the funnel as anterior Following the account of the two small but important orders is a useful summary, in about twenty pages, of the principal features of structure and of life history of the Cestoda, the orders of which are then described in turn, beginning with the Tetraphyllidea (40 pages), the Diphyllidea (6 pages), and the Tetrarhynchidea (unfinished) The wealth of well drawn new figures is a feature of this part

(3) Prof Max Rauther has produced in 150 pages a useful account of the Nematoda—their structure, development, physiology, ecology, and systematics He must have been faced often with the difficult problem of what should be included and what omitted, and on the whole he has chosen judiciously Many readers would have welcomed a somewhat fuller treatment of free living Nematodes, for the emphasis in this work is on the parasitic forms Instead of the brief reference to diminution of chromatin we should have preferred a short illustrated account of the chromosomes of *Ascaris* and their history during the early cleavages of the egg, to bring out, as this case does so well, the principle of the germ-track

(4) The major portion of this part is devoted to a description by Prof Bresslau of the reproductive apparatus and development of *Turbellaria* It

includes an admirable account, with numerous schematic and other illustrations, of the different types of reproductive apparatus, and a description of the development of entolecithal and of ectolecithal eggs The remainder of the part deals with the physiology of movement and of the eyes This memoir on the Turbellaria promises to be the best available general account of the class

(5) Prof Rauther is also the author of the chapters on the Nematomorpha (46 pages) and the Acanthocephala (34 pages) For both groups the accounts of the different systems of organs, the life history, and systematics are well done and are illustrated by 96 figures, many of them original or from recent memoirs

The second volume of the "Handbuch", in which these five parts are included, reaches a high standard and we look forward to the appearance of the remaining parts of this volume, especially those on the Polychæta, Hirudinea, and Gephyrea

(6) Dr Handlirsch continues his account of the Insecta The present chapters deal successively with seven orders, including the Mantodea, Blattariæ, Isoptera (with some good illustrations of the nests of termites), Mallophaga, and Siphunculata The external morphology is adequately considered, but the internal organs of some of the orders deserved fuller treatment, and the systematics of both Mallophaga and Siphunculata could with advantage have been rather more extended We should have desired to see included some references to the histology of the organs and tissues and to the occurrence of symbionts there is no reference to these, and the mere remark that there are gut parasites in termites gives no suggestion of the very interesting relationships which exist between the termites and their intestinal protozoa

(7) Dr Stresemann maintains his high standard in the further description of the biology and structure of birds The major portion of this part is concerned with the food of birds and the associated structural modifications of beak, tongue, and foot the relations of birds to flowers, the storage of food, for example, by the Californian woodpecker, the processes of digestion, the biochemistry of eggs and of metabolism in the embryo, and the periodic changes in the reserve of fat The later part of the chapter deals with the anatomy and physiology of movement of the vertebral column, of the legs, and of the sleeping posture (unfinished) The author has drawn his material from a great variety of sources and has treated the subjects considered in a thorough and interesting manner

Bartholomew Sikes's System of Alcoholometry

Alcoholometry an Account of the British Method of Alcoholic Strength Determination, with an Historical Introduction written by the Author in collaboration with George H Gabb By Francis G H. Tate Pp xviii + 93 + 12 plates (London H M Stationery Office, 1930) 5s net

BARTHOLOMEW SIKES devised a system of alcoholometry which was legalised in Great Britain in 1816 for ascertaining the strength of spirits for revenue purposes and has remained in official use ever since He designed a metal hydrometer and compiled tables for use in conjunction with it, which, together, provide a simple means of determining the strength of mixtures of alcohol and water All that has to be done is to float the hydrometer in the sample of which the strength is required, observe the hydrometer reading, take the temperature of the sample and then consult the tables, where, under the temperature and against the hydrometer reading, is found the strength of the spirit Such a simple and rapid method was not devised in a moment Indeed, the Excise Department was established in 1643, nearly two hundred years before the adoption of Sikes's system, and from its inception one of its duties was the collection of taxes levied on spirits

The early part of Mr Tate's book gives an account of the development of alcoholometry in Great Britain prior to the adoption of Sikes's system In brief, the important points are the origin of the term 'proof spirit' in connexion with the early 'gunpowder test', the re invention of the hydrometer by Boyle in 1675, which led to the development of the hydrometer for spirit assaying, the legalisation of the use of Clarke's hydrometer in 1787, and the classical work of Gilpin and Blagden (*Phil Trans Roy Soc*, 1790, 1792, and 1794) on the density of mixtures of alcohol and water Here the author is traversing ground which has been covered by other writers, but so recently as 1898 Scarisbrick, an official of the Inland Revenue, wrote in his "Spirit Assaying" "Sikes does not seem to have left a scrap of information as to the principles underlying his system"' Mr Tate, however, has had access to twenty-eight manuscript note books left by Sikes, and so is able to contribute new material to the study of Sikes's system

Hitherto the only information available has been that contained in the Act of 1816 and the tables legalised by the Act These, however, contain no explanation of the basis of construction either of the

hydrometer or the tables, and a number of questions relating to these matters have been the subject of controversy and conjecture

It has been suggested that Sikes ignored the fundamental work of Gilpin, adopted a hydrometer previously designed by Boriés, prepared a skeleton table by reading this hydrometer at various temperatures in spirits made up to known strengths, and completed the tables by interpolation Mr Tate is able to show that Sikes gave considerable thought to the design of his hydrometer and made the fullest use of the accurate data of Gilpin in compiling his tables He is also able to show how the rather unusual temperature 51° F came to be employed in the definition of proof-spirit

The strength of a spirit expressed as the percentage of alcohol by volume in the spirit can only be valid for one particular temperature Proof-strength is merely a roundabout method of expressing percentage composition by volume—at 50° F 100 gallons of a spirit *n* per cent over proof contain the same volume of alcohol as $(100+n)$ gallons of proof-spirit, also at 50° F —and so proof strengths must also be defined at one particular temperature The temperature adopted by Sikes for his proof strengths was unknown, and attempts to determine it from such evidence as is available in the Act and tables have led to values ranging from 51° F to 62° F Mr Tate is able to produce evidence from Sikes's note books showing that the temperature which he actually used was 50° F

It is a well known anomaly of Sikes's system that the duty assessed on a given weight of spirit varies with the temperature at which the assessment is made, the duty charged being greater when the spirit is assayed at a high temperature that when it is assayed at a lower temperature Sikes's note books include tables of corrections which would eliminate this anomaly, but they have never been adopted for official use

The new information regarding Sikes's system which Mr Tate has made available will be of interest to many readers His book also gives an account of the preparation of revised Sikes's tables by Sir Edward Thorpe, which received Parliamentary sanction in 1915, the recent extension of the range of the hydrometer and tables legalised in 1930, and the three last chapters deal with the standardisation of hydrometers, methods of allowing for 'obscuration', and the use of the refractometer respectively A useful bibliography is given at the end of the book

One important question is not discussed in the book Metal hydrometers have very obvious disadvantages as compared with glass hydrometers, and even so long ago as 1792 Blagden advised the authorities that metal hydrometers were unsatisfactory Glass hydrometers have largely replaced metal ones for assessing the duty on spirits in India, and in industry generally, glass hydrometers are used almost to the exclusion of metal ones The relative merits of glass and metal hydrometers, however, are not discussed in the book

Plant-Dispersal

The Dispersal of Plants throughout the World By Henry N Ridley Pp xx + 744 + 22 plates (Ashford, Kent L Reeve and Co, Ltd, 1930) 63*s* net

An authoritative and comprehensive work on plant dispersal—mainly, that is, the means by which fruits and seeds of flowering plants and spores of ferns, mosses, and other cryptogams are dispersed from the parent plant—has long been a desideratum Such a work is now to hand, and we congratulate Mr Ridley on the completion of his book, which embodies the results of his own observations over many years and of a digest of the very considerable and widely scattered literature of the subject

Mr Ridley is a keen naturalist and his first hand knowledge of the vegetation of Malaya, his home for twenty years, and his visits to other parts of the world, have allowed him a wide view of his subject. In his introduction, he refers to the absence of an adequate work on plant dispersal, the more remarkable in view of its important bearing on the distribution of plants throughout the world, and as a factor in the evolution of species and genera of even more importance than modifications for insect or wind-pollination—a subject on which there are fairly complete treatises Changes in climate and environment have supplied special opportunities for the effective operation of means of dispersal, and competition between individuals of a species or between different species has also been an important factor Modifications for dispersal are of a secondary nature, in cases where there exists a tolerably complete series of genera or species the author can discover " no sudden change in Nature giving rise to modifications of fruit or seed for the purpose of dissemination The evolution of a winged or adhesive fruit or seed seems to have been gradual, and to have been effected by a reduction or accrescence of certain parts, which had a primary use not connected with dispersal "

The hairs on the ovary, a protection from rain,

may develop in the fruit into wool for wind dispersal or into spines or hooks for attachment to passing animals, and sepals may persist and enlarge to form wings or floating plates for the ripe fruit A minute and apparently trivial alteration is frequently critical for the distribution of the species The occasionally firmer texture of the funicle in seeds of *Laburnum* keeps them attached to the pod until that is blown away by the wind, thus ensuring a wider dispersal than the mere scattering of the seeds round the parent plant

The headings of the chapters are supplied by the various agents operating in dispersal—wind, water, animal, or a mechanism inherent in the plant itself Wind plays one of the most important parts, it scatters not only seeds or fruits provided with some special mechanism such as wings or plumes, but also very largely those of which the small size and lightness are the only aids to dispersal It is most effective in open country, across arms of the sea or tracts of desert In arctic regions, fruits and seeds may be blown across the ice or carried by drift ice to distant shores, "many of the arctic plants found on the summits of the mountains of temperate Europe, Asia, and America probably owed their position to wind blowing over the ice in the Glacial period" Few seeds compare in lightness with the quartz-grains which have been found 700 miles from land, but, as Wallace pointed out, their compression and irregularity of outline, offering a larger surface to the air, is a compensating factor, the absence, however, of certain widely distributed small-seeded plants from remote islands suggests that favourable conditions for their flight must be scarce

In the tropics, most of the epiphytes on the trunks and boughs of forest-trees are wind borne, though in the formation of the flora of the pollard-willows of Great Britain birds play a conspicuous part in the carriage of berries and drupes The dust-seed of orchids is produced in enormous quantity, and the occurrence of species on remote islands indicates its efficacy for dispersal Plants with plumed fruits and seeds are scarce or wanting in dense forests and on oceanic islands These are practically unable to cross large tracts of water, but fall into it after a few miles of flight Such plants are continental, mostly herbaceous, and so, quickly fruiting, can rapidly cross mountains and open country, if their fruits or seeds fall, the following blasts pick them up and carry them on Adaptations for wind dispersal are manifold and are provided by various parts of flower and fruit, an account of these occupies nearly one hundred pages of the book

The action of water in dispersal is perhaps even more important than that of wind, but the associated modifications are not so elaborate or striking. Sufficient buoyancy and a sufficiently long period of impermeability by water are almost the only requirements Both large and small seeds are frequently dispersed by rain-wash or sudden rushes of water Heavier seeds may sink and germinate at the bottom, rising to the surface as seedlings to be drifted away and stranded on a suitable bank Ice, stream, river, and flood are all effective agents in carrying fruits and seeds or large portions of a plant Mr Ridley gives a comprehensive list of river-dispersed species, with notes based on observations by himself and others Dispersal by sea is treated in an even more comprehensive manner

Exigencies of space forbid more than a passing reference to the chapters on dispersal by animals—mammals, birds, reptiles, fish, insects, and others—and the devices of the plant for effecting adhesion to the carrier, or by human agency, or some mechanism in the mature fruit from which the seeds are shot explosively A chapter on island floras indicates briefly how the various agents have operated in stocking a number of oceanic islands

To use a hackneyed phrase, the book is a mine of information, and is, moreover, eminently readable There is a remarkable absence of technical terms, though it is in no sense a 'popular' production The illustrations, by Miss M B Moss and the author, are helpful to the understanding of the many devices for transport of fruit or seed A B R

Our Bookshelf

(1) *The Fields and Methods of Knowledge a Text book in Orientation and Logic* By Prof Raymond F Piper and Dr Paul W Ward Pp xxv + 398 + xl (New York and London Alfred A Knopf, Inc, 1929) 16s

(2) *Rational Induction an Analysis of the Method of Science and Philosophy* By Dr Homer H Dubs Pp xv + 510 (Chicago University of Chicago Press, London Cambridge University Press, 1930) 21s net

(1) The two books under review have several things in common, although their scope is different The dominating purpose of Profs Piper and Ward is educational, while Dr Dubs investigates the traditional methods of proof The endeavour of Profs Piper and Ward to lead their readers to a better acquaintance with the physical universe, society and man, is not an innovation in teaching But in view of the extraordinary growth of human knowledge, it seems useful if not necessary that 'freshmen' be given a comprehensive panorama of the fields and methods of knowledge, with the view of helping their orientation and to enable

them to think for themselves In this, Profs Piper and Ward have succeeded, and their practical classification of the sciences could be read with profit even by specialists on one subject or the other

It is difficult to dispute on any point of the book if one takes into account its purpose But one cannot fail from noting the pragmatic character of its exposition For example, the importance of the calculus is denoted with reference to its applications to reality Again, in the exposition of logic, much prominence is given to induction, verification, and discovery, while formal logic is summarily treated The bibliographies at the end of each chapter, the appendix on questions and exercises, and a very good index are features which enhance the practical value of this work

(2) Dr Dubs has written a comprehensive book on inductive logic, and one which has the distinction of being accurate and clear But it is difficult to note anything in it of the importance announced by the author in his preface His main thesis is that "induction always concerns itself with the establishment of the correctness of a hypothesis or assumption The attempt to establish this hypothesis may be by one of three ways empirical induction, immediate description, or rational induction, which is the most general of them all Its very simplicity, however, has often led to its being misunderstood by those who have used it, especially by logicians, who have too often tried to assimilate it to the better recognised deductive procedure" (pp 126 127) So the author endeavours to re-state the case for rational induction, but in doing so, he hits upon scarcely anything new in the field of inductive logic T G

Joseph Fraunhofers Leben, Leistungen und Wirksamkeit Nach Quellen geschildert von Prof Moritz v Rohr (*Grosse Manner Studien zur Biologie des Genies*, herausgegeben von Wilhelm Ostwald, Band 10) Pp xx + 233 (Leipzig Akademische Verlagsgesellschaft m b H, 1929) 15 gold marks

IN this sympathetic and concise biography, Prof von Rohr has rendered yet another service to science The achievements of Joseph Fraunhofer, who was the founder of the modern technical optical industry in Germany, were too little known even in his own country

The book paints a grey picture of the optical industry at the opening of the nineteenth century, with its preoccupation in the mass production of cheap spectacle lenses and its lack of attention to more complex instruments It is suggested that English opticians owed much of their pre-eminence at that time to the demands of seamen for telescopes and the like

Whence springs genius? How could this lad with his desultory and indifferent schooling train himself to become a leader not only in technical practice, but also in those fundamental steps which mark the emergence from crudeness and haze to precision and clarity in the understanding of the underlying principles of technical optics? All the world knows of the Fraunhofer lines and their applications to exact refractometry, but how many realise the painstaking efforts at refractometry with the aid of a monochromator, the ambitious attempt to produce non-spherical surfaces of optical accuracy?

Fraunhofer belongs not to Germany alone but to the world To read this little book is to gain a clearer perspective in one's view of present-day problems, and encouragement in the patient efforts which they require L C M

Handbuch der anorganischen Chemie Herausgegeben von Prof Dr R Abegg, Dr Fr Auerbach und Prof Dr I Koppel In 4 Bänden Band 4, Abteilung 3 *Die Elemente der achten Gruppe des periodischen Systems* Teil 2 *Eisen und seine Verbindungen* B Lieferung 1 Pp Bxvi + B463 (Leipzig S Hirzel, 1930) 45 gold marks

THE high standard of all the volumes of Abegg's "Handbuch" is too well known to require comment, and it is only necessary to announce that a further volume has appeared in which the description of the elements is carried into the eighth group The rapid progress towards completion under the editorship of Dr Koppel is to be especially praised, and the way in which he has maintained the character of the work deserves the highest commendation Unlike some other comprehensive works on inorganic chemistry, 'Abegg' has always been characterised by a maturity of exposition and a critical treatment of the material which shows clearly that the contributors have not been content merely in amassing abstracts The present volume, which deals with compounds of iron, covers the field in a way which leaves nothing to be desired It will be invaluable to all chemists As in previous volumes, emphasis is laid on the physico-chemical aspects of the substances, but not to the neglect of descriptive chemistry The complex iron cyanides and colloid systems are to be dealt with in another volume

An Introduction to Regional Surveying By C C Fagg and G E Hutchings Pp xi + 150 (Cambridge At the University Press, 1930) *7s 6d* net

REGIONAL survey, as an exercise in concrete geographical study, was introduced into university education in Great Britain by the late Prof A J Herbertson under the inspiration of Prof P Geddes The methods since then have been utilised in most of the schools of geography in Great Britain, and a great deal of work has been accomplished, though relatively little has been published, largely for lack of means The authors of this small volume are enthusiasts and have themselves done good work in regional survey They set out here to explain some of the methods of field work and mapping Their aim is practical guidance, and even if they explain a good deal that will be obvious to any student of geography, they have written a useful handbook for which there is a real need There are several sketch maps and diagrams

Letters to the Editor.

Atmospheric Pressure and the State of the Earth's Magnetism

WHILE examining data for atmospheric pressure and terrestrial magnetism at various observatories of the Meteorological Office to discover possible relationships, and after meeting with no clear cut success so long as attention was confined to daily mean values of pressure, I have now obtained results pointing to a hitherto unsuspected relation between the type of the diurnal variation of pressure and the general state of magnetic conditions, as regards disturbance and quiet, over the earth As the best available index of the degree of magnetic disturbance

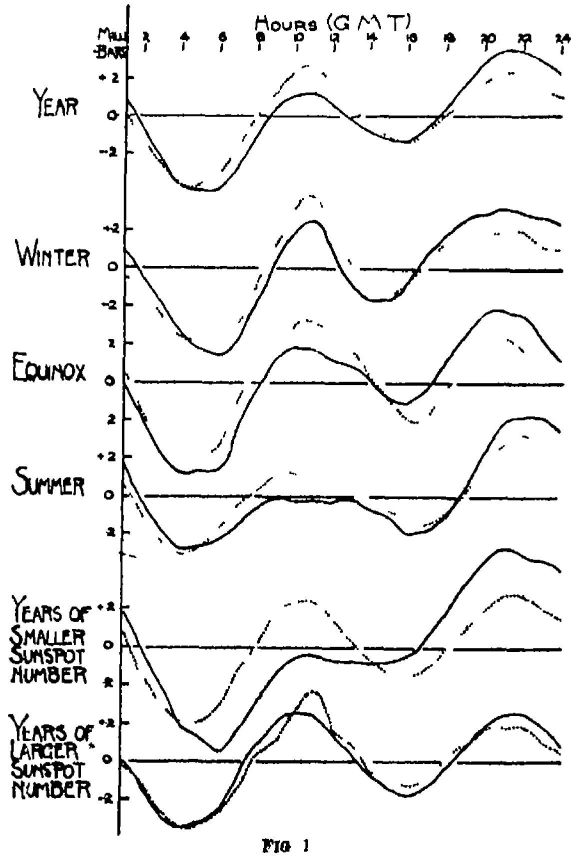

FIG 1

on each Greenwich day, the international magnetic character figure was used, the pressure data were those for Aberdeen Observatory as printed in the Observatories' Year Books of the Meteorological Office, Air Ministry Mean diurnal inequalities of pressure corrected for non-periodic change were computed for the two sets of days, magnetically quiet and magnetically disturbed, on the basis of the five days of each type per month selected at De Bilt over the seven years 1922–28

By grouping the inequalities according to the season of the year (defining winter as the four months November–February, summer the months May–August, and the remaining four months forming equinox), diurnal variations of pressure representative of the three seasons were constructed A further rearrangement of the data gave inequalities illustrating the pressure variations on the two types of days in years of low and high solar activity The mean sunspot number for the group of years 1922–24 is 12 2, for 1925–28 the mean is 63 5

The results are shown in the six pairs of curves on Fig 1 The dotted curve in each pair represents the diurnal variation of pressure on magnetically quiet days and the full curve on magnetically disturbed days The difference in form clearly shows the change in the pressure variation from one type of magnetic days to the other

From these it is clear that in all but the last pair the predominant features of the change are the reduced development of the forenoon maximum and enhancement of the evening maximum on disturbed as compared with quiet days That the effect is consistently present in each of the pairs of curves for the separate seasons as well as for the year as a whole is strong evidence of its reality The last two pairs of curves illustrating the change of form of the variation in years of relatively low and of relatively high solar activity clearly indicate that, while the change is very marked in feebly active years, it may be masked or even partly reversed in years of frequent and large sunspots

When the mean inequalities are analysed harmonically, it becomes obvious that change of form of the variation is confined almost entirely to the 24 hour wave, the amplitude and phase are both affected In each pair of magnetically quiet and disturbed day pressure variations, except that for the group of years 1925–28, the amplitude of the first harmonic on disturbed days exceeds that for quiet days The ratio of the amplitudes increases from 1 4 for the winter months to 1 7 for equinox and 2 2 in summer, in the group of years of low sunspot development it is 3 3 In all the groupings of the data there is a retardation of the 24 hour wave in passing from quiet to disturbed days, the retardation is a little more than two hours in all groups except that representing high solar activity, when it is about half an hour

Against these changes in the whole day wave the constancy of the 12 hour component is striking The ratio of the amplitudes for the two types of days remains steadily about unity in all groups and the changes in phase angle are not significant

Lerwick Observatory, Shetland

The Karoonda (S A) Meteorite of Nov 25, 1930

AT 10 53 P M on the evening of Nov 25 an extremely brilliant fire ball was seen by many observers in South Australia It was observed at Port Lincoln on the west coast, Wirrappa (94 miles north west of Port Augusta), Mount Gambier in the south east of South Australia, Murrayville in Victoria, and Broken Hill in New South Wales, the radius of observation being thus well over 250 miles

When first seen, the meteorite compared in brightness with a star of first or second magnitude, but rapidly (in a few seconds) increased to a brilliancy which gave an illumination comparable to that of daylight, even in Adelaide An amusing feature of many reports is the illusion of close proximity due to this brightness It was described by many observers as an immense ball of bluish white colour, equal in diameter to the full moon, and having a luminous tail several degrees in length As it approached the earth showers of sparks issued from the main body

Observers within a few miles of it heard a noise which is variously compared to the loud rumble of an earthquake, to the roar of a passing train, or to "the banging-together of sheets of galvanised iron" Messrs. Honeyman and Millard, of Karoonda, who were nearer the locality of the fall than any other observers (2½ miles distant), give the following account " the disappearance of the meteorite was followed by a loud detonation as though a very heavy charge of explosive had been let off underground This caused a distinct vibration of buildings near by This sound was followed, at an interval of about three seconds, by a loud crackling and rending sound from the sky in the direction in which the meteorite was last seen, then by a low rumbling of thunder which gradually died away in the distance"

The meteorite appears to have descended at a steep angle of about 70° with the horizontal When first seen it had an altitude of 150 miles or more, and the duration of its fall was approximately six seconds It travelled in an east south-east direction

A search party from the University of Adelaide and Adelaide Observatory proceeded to Karoonda on Dec 6 Two days were spent in making inquiries from local eye witnesses of the fall These enabled the locality to be determined within a radius of one or two miles, and on the third day the meteorite was found lying in a sandy fallowed wheat field, 2½ miles east of the township of Karoonda It had made a crater like hole in the sand eighteen inches in diameter and about the same depth, with a surrounding ridge of sand three feet six inches across

The meteoritic stone had shattered on striking the earth, and numerous fragments were scattered over a radius of four or five feet The bulk of its mass, however, was within the crater, the largest fragments being on the east side and pointing nearly vertically down In addition to pieces varying from an ounce or two to seven pounds in weight, there were very numerous smaller fragments and much finely pulverised material mixed with sand The whole was collected, and the meteoritic material separated from the sand in a magnetic separator The total weight of the meteorite was thus ascertained to have been 92 lb On some of the larger fragments a surface layer about one millimetre thick had obviously undergone recent fusion, and both this and other parts of the surface showed the customary 'thumb marks' and lines of flow

The meteorite is of a type unfamiliar to any persons who have yet seen it, and possibly unrepresented in Australian collections It is certainly an 'aerolite' or stony meteorite, and probably of the class termed "Chondrites" by Prior (Guide to the Collection of Meteorites—British Museum Handbook) and the sub class or group "Enstatite—Chondrites"

The material is uniformly of a dark grey, approaching a black colour, with numerous spherical inclusions (chondrules) and specks of metallic lustre, possibly troilite It is quite friable, has a specific gravity of 2·44 and a distinct 'earthy' odour A chemical analysis is in progress

Rational Logarithms

I HAVE recently been considering how best the theory of logarithms could be presented to a beginner without such a paralysing opening as used to be the practice (see Todhunter) I do not know what is done now But the result of this consideration has been the development of a complete exposition of the whole fundamental principle of the logarithm without any of the mathematical treatment which, so far as I know, is universally employed The idea, of course, is that this should be an introduction to the usual mathematical treatment, not a substitute for it.

Any discussion with beginners is nothing if not concrete, so that actual figures must be obtained I have found that this fundamental, basic, or 'low down' treatment of the subject leads directly to a very convenient approximate expression for the logarithm to base e of a number As is the case with the usual expansions, the expression becomes peculiarly simplified when it is used to find $\log(n+1)/n$ or $\log(n+1) - \log n$, and in order to keep this note within reasonable limits, I give the expression for this only This is $\log_e(n+1) - \log_e n = \dfrac{12n(n+1)+1}{6n(n+1)(2n+1)}$

This gives the logarithm with great facility and with very considerable accuracy

With $n = 10$ the error is 0·0⁷65506
$n = 100$,, 0·0¹²81284
$n = 1000$,, 0·0¹⁷8311

In obtaining the fractional expression, two very small errors are intentionally made for the sake of simplicity The first is almost exactly eliminated by subtracting $\dfrac{1}{12(n+1)^2(2n+1)^3}$, but this merely reduces the error by over correction to one eighth of what it was with $n = 9$, increasing to one quarter with $n = 1000$

The residual error is due to the second cause and as yet I have not been able to get an expression to meet it That for the first correction, however, is obtained by interesting and instructive means, not quite so easy as those employed in obtaining the original fraction

I have never seen this way of dealing with logarithms described I should have expected to find it in Hutton's introduction to his famous tables of 1794, where he discusses every method known at that date At the same time, it is difficult to imagine that so elementary a process, suitable almost for a kindergarten, is not known, or if it is, why it is not used

C V BOYS

Denaturation of Wool by Urea

IN a letter to NATURE of Nov 1, p 685, I stated that saturated aqueous solutions of urea unmasked a sulphide in sheep's wool and also extracted a sulphide from the wool These two statements were based on the observation that addition of a tenth volume of 20 per cent sodium nitroprusside solution, to suspensions of wool in such urea solutions, ten minutes after addition of a similar proportion of 10 per cent potassium cyanide solution (to reduce any –SS– to thiol groups), always led to the development, both in the wool and in the liquid, of a strong pink or magenta colour precisely like that of Arnold's nitroprusside reaction for organic thiol compounds, although in control tests wool not treated with urea developed only a feeble pink, and urea solutions which had not been in contact with wool developed none at all

I write now to say that the conclusion that the urea solution had extracted a sulphide from the wool was erroneous, for subsequent work has shown that the apparently typical thiol reaction obtained in the extracts was due entirely to a hitherto unknown, and at first very elusive, reaction between urea and some derivative of sodium nitroprusside, previously formed in its solution as a result of an obscure change which may for temporary convenience be referred to as 'ripening' If the nitroprusside solution is ripe enough, this reaction with urea will become obvious

within a few minutes, though it may take a long time to attain its maximum With unripe nitroprusside solution, it may require any time up to two hours to begin, or it may fail altogether It occurs only if the test mixture is alkaline but not too strongly so, and only if ammonia is absent It is quicker and more intense the stronger the urea solution, but is recognisable in 2 per cent solution It can be distinguished from a true thiol reaction by the fact that on addition of ammonia the colour soon fades to yellow In the light of these observations, it is now evident that in my former experiments the nitroprusside solutions used when testing the extracts of wool must have been fully ripe, and that used in testing the control urea solutions must have been much less so The wool itself would react equally strongly with either solution

I have made only incidental observations on the process of ripening An approximately neutral 20 per cent nitroprusside solution is sometimes adequately ripe after it has stood twenty four hours, but the time required varies greatly in different glass vessels, and the solution usually improves up to at least a fortnight No deposit is formed, and the only obvious change is a slight yellowing Ripening is much quicker in the presence of 1 per cent of sodium bi carbonate, but if such a solution is saturated with urea it soon undergoes a change, as a result of which it will turn blue or green when acidified with hydro chloric acid containing ferric chloride, although the ripe solution does not give this reaction by itself

While still exploring the conditions necessary for this 'pseudo thiol' reaction, and contemplating the possibility that it might be responsible also for the apparent thiol reaction given by the urea treated wool, I received from Dr Rimington, of the Woollen Industries Research Association at Leeds, a letter saying that wool which he had treated for twenty four hours with saturated urea solution and then washed in water refused to give a thiol reaction His procedure had been to suspend the washed urea treated wool in saturated ammonium sulphate solution, then reduce it by adding sodium cyanide up to 0 55 per cent, and after ten minutes add fresh nitroprusside solution and ammonia In my own procedure the wool had always been reduced by 1 per cent potassium cyanide solu tion while still in the urea solution, and had hence been exposed during ten minutes to a markedly alkaline urea solution Also, the Arnold test had always been applied in the presence of urea and with out addition of any ammonium compound, conditions under which a pseudo thiol reaction might conceivably occur

I have accordingly made a further set of experi ments, in which comparisons were made between the intensities of the Arnold reaction given by wool which had been treated with saturated urea solutions alkalised to different extents by addition of suitable salts, and in which any pseudo thiol reaction was pre cluded by applying the Arnold test only after the wool had been washed during twenty four hours with large volumes of water, and then reduced in 1 per cent potassium cyanide solution for ten minutes, after which a little ammonium sulphate was added to the cyanide suspension, followed by freshly made nitroprusside solution The results show that any apparent thiol reaction given by the wool thus tested is a genuine one, and also that more sulphide is unmasked in ten minutes by urea solution containing 1 per cent potassium cyanide solution, or half per cent sodium carbonate, than in twenty four hours by 1 per cent potassium cyanide solution or in ten minutes by half per cent sodium carbonate, or in twenty-four hours by approximately neutral urea solution The experiments do not show, however, whether neutral urea solutions unmask very little sulphide or none at all, for I have been unable to find wool which does not give at least a slight Arnold reaction after reduction in 1 per cent potassium cyanide solution and it is impossible to attach significance to slight contrasts in the intensities of the colours, since these often fade rapidly when the wool is removed from the test-liquids Comparing wools which have been exposed during ten minutes to a temperature of 100°, one in water, the other in saturated urea solution, there is, however, a great contrast, only the latter becomes intensely pink As the liquids become feebly alkaline during the heating, this experiment does not show the effect of neutral urea solution My former bald statement that saturated urea solutions unmask a sulphide in wool should accordingly be qualified by addition of the words "at least when they have more than a certain alkalinity"

In the case of egg albumin treated with urea, where Hatton and I took as a measure of the amount denatured the percentage of protein rendered insoluble in 27 per cent ammonium sulphate solution, we found that when the cH of the saturated urea solution was approximately that at which egg-albumin is isoelectric, the rate of denaturation was a minimum and very slow, and that the more remote the cH was from this, the quicker was the rate, especially on the alkaline side none of the alkalinities or acidities concerned was so great as to bring about more than negligible denaturation in the absence of urea I have not ascertained whether any similar relation would hold good for wool when the unmasking of sulphide is taken as a measure of denaturation, but the results referred to earlier strongly suggest that it would at least be true for such variations in cH as lie on the alkaline side of the hydrion concentrations common in distilled water W RAMSDEN

Agricultural Field Experiments

MR HOWARD's letter in NATURE of Jan 31 (p 166) gives interesting confirmation of the reviewer's opinion in NATURE of Nov 29, p 843, that depth of sowing influences the yield of wheat, yet I venture to suggest that such an extreme case as he quotes scarcely bears upon the point at issue When seeds do not germinate, it is equivalent to a light seeding rate, which, as I pointed out, makes wonderfully little effect on the yield Whether such differences as one may expect to occur between the depths of coulters in the same drill make any appreciable effect on the yields of the different rows is still, I think, an open question, and I suggest that the differences which the reviewer has observed between the yields of his rows may have been due to their being unevenly spaced The yield which is comparatively unaffected by seeding rate, is that per areal and not that per linear unit The reviewer quotes "an apparently uniform field" at Aarslev as upsetting my view that for practical purposes randomness can be obtained from the half-drill strip "provided care is taken to drill across ploughman's 'lands'", if they exist, yet Dr Sanders in his account of that experiment makes no mention of an "apparently uniform field" (*Journal Agricultural Science*, **20**, p 65), but writes, "This oscillation apparently arose as a legacy of the old practice of ploughing in high ridges", and so on

Even if the unsuitability of the field had been overlooked, the Aarslev plots were probably a good deal wider than drill width, and half-drill strips would have been extremely unlikely to coincide both in breadth and phase with the periodicity in question, while any

partial coincidence would have betrayed the existence of the snare.

Finally, there is a fallacy in Mr Howard's last sentence—"It is obvious in such questions that nothing can be gained by the application of formulæ and figures to the results obtained by poor agriculture" There is no question, of course, of connecting the half-drill strip method of experimenting with poor agriculture, its great merit lies in the fact that in its present form it is ordinary farming practice if, however, that practice were poor agriculture, it would be a mistake to carry out trials by methods conforming to better standards field trials must be capable of being considered a random sample of the practice, not of the theory, of agriculture

This may seem a hard saying, but an example will make my meaning clear After a long series of experiments the Irish Department of Agriculture decided to introduce Dr Hunter's Spratt Archer barley as being the best suited for the country This was almost everywhere a great and outstanding success, yet in one district, which shall be nameless, the farmers refused to grow it, alleging that their own native race of barley was superior to it After some time the Department, to demonstrate Spratt Archer's superiority, produced a single line culture of the native barley and tested it against the Spratt Archer in the district in question To their surprise, they found the farmers were perfectly right the native barley gave the higher yield At the same time the reason became plain the barley in question starts more quickly and is able to smother the weeds, which flourish in that not too well farmed land, Spratt-Archer, growing less strongly at first, is, however, the victim and not the conqueror of the weeds, and the original experiments, carried out on well farmed land, were definitely misleading when their conclusions were applied elsewhere

Taught by experience, the Department is now engaged in breeding a barley to meet these conditions, and this barley, when obtained, will rightly be tested by "results obtained by poor agriculture"

STUDENT

REFERRING to the effect of increased depth of sowing, "Student" writes "When seeds do not germinate, it is equivalent to a light seeding rate" This is true, but changes in depth of sowing give rise to changes not only in the percentage germination but also in the time of germination It is my experience that yield may be affected by both these factors.

My description of the field at Aarslev as "apparently uniform" would seem to be justified by Dr Sanders' statement that "This oscillation *apparently* arose as a legacy of the old practice of ploughing in high ridges" (italics mine)—appeal was made to the history of the field for an explanation of the curious periodicity

I am in complete agreement with the concluding part of "Student's" communication, summed up in his own phrase, "field trials must be capable of being considered a random sample of the practice, not of the theory, of agriculture" This is too often overlooked by those who use special machinery and methods for field experimental work

THE WRITER OF THE ARTICLE

Vacuum Spark Spectra to 40 A.: the Spectra of Be III, Be IV, B IV, B V, and C V.

THE series of hydrogen and helium-like spectra, which was previously traced [1] to Be IV, has now been completed with B IV, B V, and C V, and the limit of optical spectra brought down to 40 28 A

The vacuum spark was produced by a capacity of 0 3 μF charged to 60,000 volts Half an hour with about 30 sparks a minute was sufficient for an exposure The plates were taken with the same metal grating as was used before,[1] but now set up in a new spectrograph at a glancing angle of 5 4° Comparing the results with those from a glass grating [2] at 6°, there seems to be no reason to prefer this material to speculum metal in the shortest wave length region

Fig 1, *a*, shows the spectrum obtained with metallic

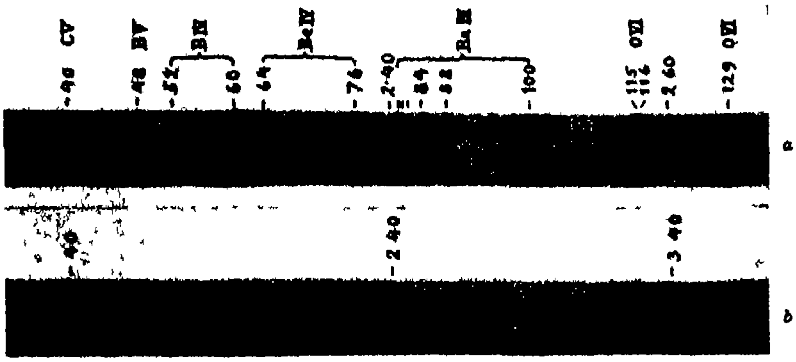

FIG 1

beryllium as the negative electrode against a tube of Acheson graphite filled with boron nitride A spark between pure graphite electrodes gave the spectrum of Fig 1, *b*, consisting of one single carbon line at 40 A in the first three orders

Of the series $1\,^2S - n\,^2P$ in the hydrogen like spectra, there appear two lines of Be IV and one of B V The wave lengths in the table were calculated with regard to the fine structure according to the formula given by Penney,[3] and used as standards

	Be IV		B V	
	ν	λ	ν	λ
$1\,^2S - 2\,^2P$	1,317,084	75 925	2,058,247	48 585
$1\,^2S - 3\,^2P$	1,560,962	64 063		

As shown in the second table, the helium-like series $1\,^1S - n\,^1P$ is considerably more strongly developed The relative intensities can be estimated from Fig 1, *a*

	Be III		B IV		C V	
	λ	ν	λ	ν	λ	ν
$1\,^1S - 2\,^1P$	100 26	997,500	60 31	1,658,100	40 28	2,482,600
$3\,^1P$	88 30	1,132,500	52 68	1,898,300		
$4\,^1P$	84 75	1,179,900				
$5\,^1P$	83 19	1 202 100				
$6\,^1P$	82 37	1,214,000				

From the series of Be III the quantum defect for the ^1P terms is calculated as $n - n^* = -0\,013 \pm 0\,001$ A comparison with He I and Li II indicates the numerical value to be constant or slightly diminishing with increasing atomic number The simple assump-

tion of the same quantum defect for Be III, B IV, and C V gives the following term values

	B IV	C V
$n - n^*$	$-0\,013 \pm 0\,002$	$-0\,013 \pm 0\,003$
$2\,^1P$	$433\,300 \pm 900$ cm^{-1}	$677{,}000 \pm 2000$ cm^{-1}
$3\,^1P$	$193\,400 \pm 300$,,	
$1\,^1S$	$2091\,500 \pm 1400$,,	$3{,}159{,}600 \pm 3300$,,

The ionising potentials $1\,^1S \times 1\,234 \times 10^{-4}$, are in good agreement with the quantum theoretical values given by Hylleraas [4] in the formula

$$\mathrm{I\,P} = Rh\left(Z^2 - \frac{5}{4}Z + 0\,31455 - 0\,0147\,\frac{1}{Z}\right),\ Rh = 13\,54$$

	B IV	C V
I P spectr	$258\,1 \pm 0\,2$ volts	$389\,9 \pm 0\,4$ volts
theor	$258\,09$,,	$390\,12$,,

It is hoped that the accuracy will be considerably increased by measurements in higher orders and a more confident determination of the ^1P terms

From the resonance line of C V at 40 A the region is completely bare of carbon lines up to 200 A, where the principal series $2\,^2S - n\,^2P$ of C IV forms the limit of the L electron spectrum Then, including spark spectra of sufficiently high orders, the wide separation between the K and L spectra, typical for the X rays, will also appear in optical spectra

Fluorescence of Mercury Vapour under Atomic and Molecular Absorption

IN the letter which appears in NATURE of Jan 3, p 10, Lord Rayleigh discusses the excitation of the green fluorescence of mercury vapour by wave lengths near the resonance line λ2537 The discontinuity of intensity of the fluorescent radiation along the beam of the exciting light leads him to admit the atomic as well as the molecular absorption The hypothesis of two kinds of absorption exciting the fluorescence was further confirmed by Lord Rayleigh's investigation of the influence of the hydrogen admixture These experiments support the view that the fluorescence of mercury vapour is chiefly due to atomic absorption

I should like to point out that this conclusion agrees with that which I have drawn from my experiments on the influence of the magnetic field on the fluorescence of mercury vapour [1] In these experiments the fluorescence was excited by the light of the mercury line λ2537 The tube with the distilling mercury vapour was placed between the poles of a powerful electromagnet and the intensity of the fluorescent radiation was observed at different strengths of the magnetic field as measured at the place of excitation The variation of the intensity of the green fluorescence was found similar to that of the resonance radiation investigated by M Schein [2] The maxima and minima of the intensity of both radiations appeared at equal magnetic fields, thus indicating that the region of the excitation of the fluorescence has exactly the same hyperfine structure as the exciting line λ2537 Hence the only possible conclusion seemed to be that, in the excitation of the fluorescence of mercury vapour at moderate densities by the line λ2537, the atomic absorption forms the first necessary step of the excitation.

The evidence of my experiments referred to above and the recent work of Lord Rayleigh are decidedly against the view often expressed that the fluorescence of the mercury vapour should be produced by the molecular absorption alone

Raman Spectrum of Hydrogen Peroxide

THE Raman spectrum of hydrogen peroxide (Merck's perhydrol 30 per cent solution in water) has been photographed The prominent feature of the spectrum is the presence of a sharp Raman frequency of 875 accompanied by a weak component at 903 The low value of the frequencies suggests that they arise from the oxygen atoms, and as such may be compared with the O_2 oscillation frequency 1552 obtained by McLennan (*Trans Farad Soc*, 25, 798, 1929) The large difference between the two values is indicative of the fact that the oxygen atoms in hydrogen peroxide (H_2O_2) and oxygen (O_2) molecules respectively are bound differently Besides the above two frequencies, there appear other bands which are less intense and sharp, the origin of which is under investigation A detailed discussion of the results obtained in relation to the structure of the molecule will appear elsewhere

Resistance of *Eurytemora hirundoides* Nordquist, a Brackish Water Copepod, to Oxygen Depletion

THE River Tyne estuary is polluted by crude sewage and manufacturing effluents to such an extent as to cause a serious depletion in dissolved oxygen It is not unusual to find a complete absence of dissolved oxygen on isolated occasions during the summer months The number of normal estuarine organisms able to withstand these adverse conditions is very limited [1] Of these, *Eurytemora hirundoides* is the most abundant and the most hardy Its region of maximum abundance lies between 9 miles and 13 miles from the river mouth, in the area of heaviest pollution and most noticeable oxygen depletion At a survey held on July 22, 1925, it occurred plentifully in regions where the dissolved oxygen was nil, as determined by the Winkler method [1,2] During 1929 I obtained it freely in the water sampler on occasions when the oxygen content was again nil (these remarks apply to the sampling depth of 6 ft)

There are, at the present time, several investigations being made into the oxygen requirements of certain marine animals It may, therefore, be of interest to place on record the following additional observations upon *Eurytemora*, made incidentally in the course of other work

In addition to determining the dissolved oxygen *in situ* of the River Tyne at Newcastle, I have for the past two years included an additional test described as the 'dissolved oxygen absorbed' This is a modification by Jackson and Jee of the test recommended by the Royal Commission on Sewage Disposal [3] A stoppered bottle of approximately 330 c c capacity is filled with the river water (taking the usual precautions to exclude all air) and 'incubated' by complete immersion in water at air temperature for a period of seven days The oxygen remaining is de

termined Under existing pollution conditions, there are but few occasions in the summer when the residual oxygen exceeds nil Varying numbers of *Eurytemora* are usually present in the river water when sampled, and are thus included in the sample put aside for this test The following table gives a record of the ensuing mortality on these included copepods for certain dates during 1930

Date sampled	Oxygen *in situ* (gm per 100,000 gm)	Oxygen remaining after incubation (gm per 100,000 gm)	*Eurytemora*
May 23	0 44	0 045	Most alive, some dead
May 30	0 24	nil	All dead
June 6	0 26	nil	All dead
June 13	0 14	nil	All dead
June 20	0 33	nil	All dead
Aug 1	0 50	0 004	Most dead, a few alive
Aug 8	0 76	0·45	All alive
Aug 15	0 74	0 006	Few dead, most alive
Sept 5	0 58	0 004	7 present at start, 7 still alive

It is to be noted that on four of the nine occasions the dissolved oxygen has been completely utilised by oxidisable matter, and no *Eurytemora* remained alive Toxic substances may have exerted an influence in addition to oxygen deficiency It is evident that, although the copepod is regularly taken in the river under such conditions, it can survive total oxygen deprivation for short periods only Its presence in the river at these times may be explained by the continual slight aeration of surface waters by river traffic, slight though the effect may be It is clear from the table that this copepod may survive in brackish water, heavily polluted, when the oxygen concentration is no more than 0 004 gm per 100,000 gm

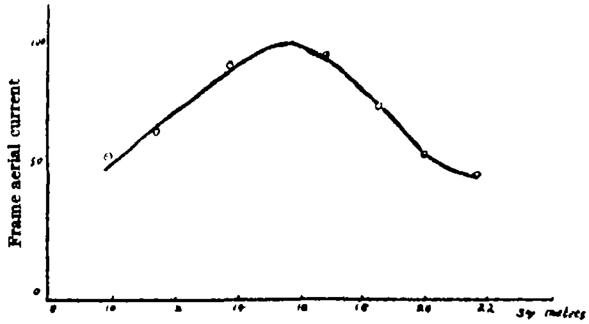
Optimum Dimensions of Short-wave Frame Aerials

BECAUSE of the increasing use of short waves in present day wireless practice, many investigators have studied the nature of the electromagnetic field at distances less than a wave-length from a radiating antenna The importance of such investigations lies in the fact that a knowledge of the peculiarities of the field at these short distances enables designers of directive beam aerials to space correctly the units of the radiating and receiving systems For example, for maximum forward radiation the critical spacing between a line of tuned radiating antennæ and a line of tuned reflecting wires is now known to be 0 33 or 0 85 of a wave-length and not 0 25 of a wave-length as was originally supposed [1]

The erroneous argument which leads to the result that 0 25 of a wave length is the best spacing between a Hertzian dipole oscillator and a reflecting antenna behind it, also leads to the conclusion that the best width of a frame aerial is 0 5 of a wave length A more rigorous theoretical treatment shows that, for a frame aerial, there are several different critical widths and heights which depend upon the wave-length in use, and that none of these critical values is half a wave length Although the critical dimensions are of little consequence in long wave work, they are of outstanding importance in the design of frame aerials for short waves, because the resulting current for tuned aerials can be increased many thousandfold by designing the frame with the optimum dimensions Thus a square or circular frame is always less efficient than a correctly proportioned rectangular or elliptical frame of the same area

Since both the optimum width and height are dependent on the wave length, it follows that the optimum area of a frame is also critical when used for wave lengths comparable with the dimensions In the current literature it has been assumed hitherto that the larger the area of the frame, the greater will be the radiated power or the received current, but this is not so for short waves Investigations upon which we are now engaged have shown, for example, that it is possible to double the area of a tuned frame without increasing the signal strength, even when the ratio of the height to the width is the optimum value for the particular wave length in use This is shown in the accompanying graph (Fig 1), which is based



Area of frame with optimum dimensions

FIG 1

on measurements made on 8 65 metres with a tuned frame capable of being expanded in either or both dimensions The current values are those obtained when the frame was adjusted to its optimum dimensions, and hence the currents recorded are the greatest that can be obtained with a frame of the given area Thus the greatest possible current was approximately the same whether the area of the frame was 10 or 20 square metres, and this current was reduced by any change in the relative dimensions of these frames The critical area was between 15 and 16 square metres, and then the maximum current exceeded that for frames of any other area In all cases the frame was tuned to 8 65 metres

A further point of interest is the fact that a frame designed for best reception on a given wave length is not the optimum shape for maximum radiation on the same wave length

As we have ventured to think that these preliminary results may be of some interest, it was thought desirable to write this brief note now, but it is proposed to publish the work in detail shortly, when the theoretical and experimental investigations now in progress are completed

The Manchester Literary and Philosophical Society

By C L BARNES, Honorary Librarian

THE centenary of a society being by common consent an occasion for pride, encouragement, and hopeful anticipation, it follows that at a sesqui centenary these accompaniments should enjoy a proportionate increase With this advantage in prospect, the Manchester Literary and Philosophical Society, founded in February 1781, will celebrate its one hundred and fiftieth anniversary on Tuesday, Mar 17, when Sir J J Thomson—himself a native of Manchester and an alumnus of Owens College—will deliver an address at 4 P M in the Athenæum Hall An honorary member since 1895, he will be presented with the Society's Dalton Medal, the last award of which was made in 1919 to Lord Rutherford, who, but for the call to Cambridge, would have been president for that and the following year There will be a dinner the same evening in the Midland Hotel at 8 P M During the week, after Tuesday, the Society's house, No 36 George Street, will be open to visitors from about 11 A M to 5 P M

The Society is one of the oldest of its kind in existence Excluding the Royal Society, and various State aided academies in Continental capitals, which are not on the same footing, there are less than half a dozen provincial scientific societies in the world with so long a history The house, purchased in 1799, has externally an old world appearance, with pillars in front and a porch, finely panelled in mahogany Internally it is most attractive, and preserves an atmosphere of studious calm in a district long ago given up to commercial activities There are portraits in oils of Newton and Davy—copies of those in possession of the Royal Society—of Percival, Dalton, Joule, and other past presidents marble, bronze, and plaster busts, and a large number of engraved portraits or photographs of distinguished men of science

Of Dalton relics the Society has an unequalled collection Here are to be seen nearly all the crude chemical apparatus with which he worked, his meteorological observations, begun at Kendal, and continued for more than fifty years, many MSS of his papers, an orrery, a planetarium, and electrical appliances, his medals, including the Copley Medal of the Royal Society, and a few articles of personal property

Dalton came to Manchester in 1793, as 'professor' of mathematics—in which he had some skill—at the then new Manchester Academy He joined the Society in 1794, and read more than a hundred papers during his half-century of membership From 1816 until 1844 he was president, but had previously filled almost all the other offices He supplemented an exiguous income by taking pupils (at *1s 6d* a lesson), by lecturing, and writing books One on "The Elements of English Grammar" (1801) is said to have given him special satisfaction Though none but caretakers ever lived in the house, Dalton was allowed the free use of a room in it, and a marble tablet commemorates the fact that here, out of his experiments and cogitations, the atomic theory was developed

One of Dalton's pupils, though a paralytic stroke brought the tuition to a premature end, was James Prescott Joule, who worthily upheld the Society's prestige for about thirty years after Dalton's death in 1844 Two of the thermometers, with very large bulbs, very narrow bores, and nearly a yard long, used by Joule in his researches, are still carefully preserved, and when compared with a standard Tonnelot thermometer by Sir Arthur Schuster, about forty years ago, were found to be surprisingly accurate *

The Society found a liberal benefactor in Dr Henry Wilde, whose name is inseparably associated with the dynamo He enlarged, improved, and strengthened the premises, and provided a substantial endowment

Though these three names are more closely connected with the Society's history than any others, the bond between it and Owens College, afterwards the Victoria University of Manchester, which began in 1851, has always been very close Among presidents from one or other of these bodies may be mentioned Roscoe, Crawford Williamson, Balfour Stewart, Sir Horace Lamb, Osborne Reynolds, Sir W Boyd Dawkins, H B Dixon, F E Weiss, Elliot Smith, S J Hickson, Sir Henry Miers, and W L Bragg

Nor have distinguished non academic members been wanting To dive into the past for a moment, Dr Thomas Percival, M D, F R S, the leading spirit among the founders, and president for several years, was a friend and correspondent of Benjamin Franklin, two of whose communications, on meteorological matters, were read in 1784 The Rev William Gaskell, whose sterling merits have been eclipsed by his wife's greater fame, was a member, and William Sturgeon, inventor of the electro-magnet, also William Henry (Dalton and Henry's law is still on the chemist's statute book), Stanley Jevons, and James Nasmyth, of steam hammer fame To these may be added the Rev T P Kirkman (a distinguished mathematician whose name recalls the problem of the fifteen school-girls), John Hopkinson, Sir Joseph Petavel, and H J G Moseley, whose untimely death in the War is still mourned, and even so the list is incomplete It is worthy of note that Eaton Hodgkinson and Sir W Fairbairn, both presidents in their day, were the two upon whom Robert Stephenson chiefly relied when planning the Britannia and Conway tubular bridges, one worked out the calculations, the

* The secular rise in the freezing point of these instruments was examined both by Joule and Schuster A more recent test by Dr J. R. Ashworth (*Journal of Scientific Instruments*, Nov 1930) shows that in the principal thermometer the reading is 15 48 of the arbitrary scale-divisions, or 0 66° C higher than in 1844 it appears to be approaching a limit exponentially

other provided the metal work In more recent times, R D Darbishire, Sir W Bailey, Charles Bailey, Cosmo Melvill, and Dr H Levinstein have occupied the chair Mr C E Stromeyer has held office since 1929

The Society issues an annual volume of *Memoirs and Proceedings*, and many valuable papers are enshrined therein, as is testified by their inclusion in the Royal Society's catalogue

A special lecture, to which a premium is attached, is given once a year, and such men as Sir George Stokes, Sir Michael Foster, Sir William Ramsay, Dr Elie Metschnikoff, Prof F Soddy, the late Lord Rayleigh, Sir Joseph Larmor, Sir Charles Parsons, Sir William Bragg, and others of equal note, have responded to the Society's invitation Sir J J Thomson's name is still to be added

No mention of the Society would be complete without a reference to its library of 44,000 volumes, consisting mainly of the transactions of other scientific societies and institutions throughout the world These have been acquired by purchase or exchange over a very long period, and in most cases are complete, or nearly so The library is an outlier in connexion with the National Central Library

It is hoped by this celebration to extend the Society's influence and membership, and to make more widely known a record of which it has every reason to be proud

Experiments in Locomotive Design

IN a paper on "High Pressure Locomotives", read before a crowded meeting of the Institution of Mechanical Engineers on Jan 23, Mr H N Gresley, the chief mechanical engineer of the London and North-Eastern Railway, gave an account of the various high pressure locomotives constructed in the United States, Germany, Switzerland, and England since 1924 Prefacing his remarks by observing that at no time during the history of the steam locomotive have such radical changes been introduced as during the past ten years, he said that in Great Britain alone there are 23,000 locomotives, on which a sum of £45,000,000 per annum is expended on maintenance, renewal, and running About 25 per cent of this is the cost of fuel and another 25 per cent the cost of maintenance and renewal It will be noted that the expense in maintaining locomotives is equal to the cost of the great quantity of coal they consume From this it is clear that there is a wide field for economy if both the cost of fuel and maintenance can be reduced

In locomotives with the type of boiler as developed from that incorporated in the *Rocket* by Stephenson, boiler pressures up to 325 lb per sq. in have been experimented with but 250 lb per sq in is approximately the maximum pressure which can be carried in such boilers, having regard to the cost of maintenance It took a hundred years to increase the pressure from 50 lb to 250 lb, but during the last few years pressures have leapt up to 450 lb, 900 lb, and even 1700 lb But while high steam pressure gives greater economy in fuel consumption, it demands complications in design, and care has to be taken that the economies in fuel are not absorbed in the increased cost of maintenance of the boiler and of the machine as a whole In all the latest high-pressure locomotives, reciprocating engines have been adopted and the use of a compound engine or of a uniflow engine is essential Two-, three-, or four-cylinder compound engines have all been used in one or other of the engines described

In the United States, the Delaware and Hudson Railway in 1924 built a main line locomotive with 325 lb pressure with a two-cylinder compound engine This locomotive, named the *Horatio Allen*, was followed by the *John B Jervis* (1927) with 400 lb pressure and the *James Archbald* (1930) with 500 lb pressure The weight of these engines is between 150 and 160 tons In all three locomotives the barrel portion of the boiler differs little from the usual type The firebox, however, is formed by flat front and back water spaces joined by four circular drums two upper and two lower At the two sides of the firebox space are water tubes connecting the upper and lower drums, while the roof of the firebox is formed of tubes joining the front and back water spaces With this type of boiler about one third of the evaporative heating surface is in the firebox, instead of only about one tenth as in the ordinary boiler Superheaters are used giving a steam temperature of 700°-750° F

The German engines are known respectively as the Schmidt Henschel three cylinder compound locomotive and the Schwartzkopff-Löffler three-cylinder locomotive The first Schmidt-Henschel locomotive was built in 1926, and since then four others have been completed or are under construction The high pressure locomotive of the London, Midland, and Scottish Railway is of this type Four of the engines work with steam at 850 lb and the other at 900 lb The boilers of these locomotives consist of two—or, perhaps more correctly, three distinct parts Steam for use in the cylinders is generated in two separate boilers working at 850 lb and 200 lb respectively, but the greatest novelty in the arrangement consists of the method of heating the high pressure boiler All around the firebox are water tubes which are connected to elements in the high pressure boiler, the elements and the tubes forming a closed circuit partially filled with distilled water Owing to the heat of the fire, saturated steam is generated in this circuit at 1200 1600 lb pressure, and this very high pressure steam is used as a medium for heating the water in the high pressure boiler One advantage of this arrangement is that, owing to the use of distilled water, there is no scaling or corrosion to cause overheating of the tubes The weight of the first Schmidt Henschel locomotive was only 91 tons, but one now under construction for the Canadian Pacific Railway will have a weight of 206 tons

The Schwartzkopff-Löffler locomotive with steam at 1700 lb pressure is of still more novel construction The boiler is a most complicated system of tubes and drums with a very large number of joints and connexions, and it is difficult to believe that such arrangements can ever become standard practice Here again there are two distinct boilers, one working at 1700 lb supplying steam to the two high pressure cylinders and the other working at 225 lb pressure supplying steam to the single low pressure cylinder Neither of these boilers is subjected to the heat of the fuel or gases, the heat for the high pressure boiler being obtained from highly superheated steam generated in a high pressure superheater surrounding the fire box, while heat for the low pressure boiler is obtained from the steam exhausting from the two high-pressure cylinders The locomotive of this type was built for the German State Railways in April 1930, but is apparently not running at the present time

The Swiss engine known as the Winterthur high-pressure locomotive was completed about the end of 1927 The locomotive weighs about 90 tons and is fitted with a three-cylinder uni flow engine with cam-operated poppet valves, and exhaust passages round the middle of the cylinders Steam is generated at 850 lb pressure in a water tube boiler with one large upper drum and two small lower drums Walls of water tubes form the sides of the firebox and other water tubes partially fill the flue space, which also contains a superheater and a feed heater Trials of the locomotive have been made in Switzerland, Austria, and France, and during some recent runs a coal consumption of about 2½ lb per draw bar horse power was recorded

About half of Mr Gresley's paper was devoted to the American, German, and Swiss locomotives, while in the second part he gave an account of the locomotive No 10,000 which has been built to his designs for the London and North-Eastern Railway The steam pressure in this locomotive is 450 lb per sq in Completed in 1929, No 10,000 has since worked trains of more than 500 tons weight for long distances at express speeds with consistent success and reliability There are indications that it will prove more economical in fuel than express engines of the normal type, but economy in maintenance costs will only be apparent after the engine has run for some years In this locomotive there are two high pressure cylinders and two low pressure cylinders As in the other locomotives, the greatest interest lies in the boiler, which is the outcome of the collaboration of Mr Gresley with Mr Harold Yarrow The boiler (Fig 1) is essentially a variant of the well-known and very successful boiler first invented by Sir Alfred Yarrow for fast naval vessels In locomotive No 10,000 there is a single upper steam drum about 28 ft in length and 3 ft in diameter and two pairs of lower water drums 11 ft and 13½ ft in length respectively—one pair for the sides of the firebox and one pair for the sides of the flues Curved water tubes run from the four lower drums to the upper drum The distances between the steam drum and the water drums at the firebox end of the boiler are such that the lines joining the centres of the drums approximately form an equilateral triangle The water drums in the flue space are much closer together One interesting feature of the design is the method of supporting the upper drum from the engine framing, so that while it is prevented from moving vertically or laterally, it can expand and contract longitudinally, while another is the means adopted for ensuring the deposition of the mud in the drums and not in the tubes Experience has shown that the boiler can be worked for a much longer period than the ordinary type of boiler before requiring washing out, and although there are 1536 points at which the tubes have been expanded into the drums, there has been no case of leakage

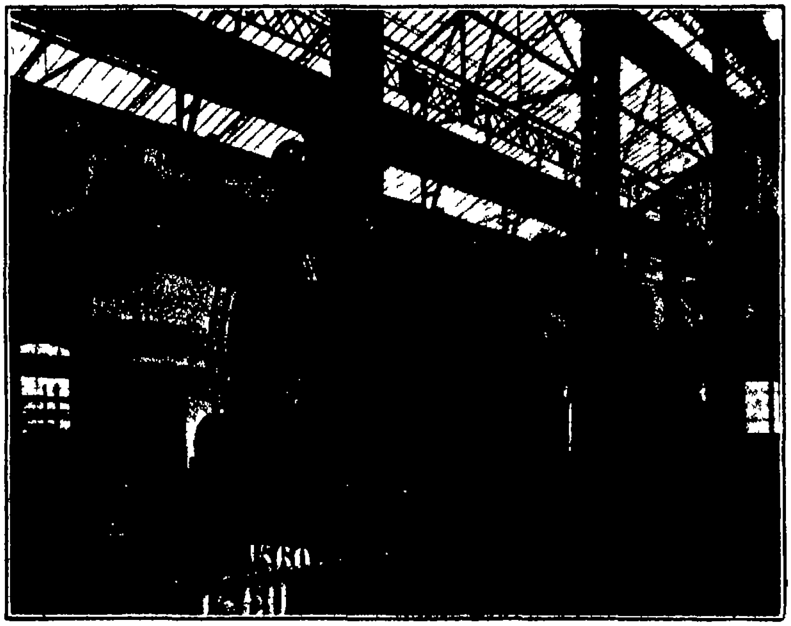

FIG 1 —Boiler, constructed by Messrs Yarrow and Co, Ltd, of the L N E R locomotive No 10,000 By courtesy of Messrs Yarrow and Co, Ltd

The ancillaries to the boiler include a feed heater and a superheater, while by surrounding the whole boiler with a double casing through which the air can circulate, all the air for combustion can be preheated to about 250° F

A feature of the locomotive which has caused public comment is the forward end, where a short funnel is housed between blinker plates This arrangement was adopted as the result of experiments made by Prof W E Dalby with the object of finding some means of keeping smoke and steam clear of the cab windows

Water Pollution Research

MAINTENANCE of the purity of our rivers and streams becomes of increasing social importance with the growth of industry, of population, and the consequent use of water to carry away waste products

On one hand is the desire to preserve the amenities of the country, to preserve fisheries providing open air recreation to many and a valuable yearly yield of salmon from several of our rivers, to meet the increasing demand for water of good quality for domestic and industrial use requiring neither expensive treatment to free it from the effects of pollution nor long and expensive pipe lines to bring it from distant unpolluted sources

On the other hand lies the necessity of disposing of sewage and trade effluents in the most economical manner, without overburdening the rivers with putrefiable or poisonous discharges Rivers can deal with relatively large quantities of such discharges, since they are soon oxidised after sufficient dilution in a stream of well oxygenated water, but when this is overstepped, death of fish, noxious smelling by-products, and the growth of fungus on the river bed result

Publicity has done much to allay the natural increase of harmful pollution during recent years Many problems have arisen When does pollution become so harmful that it is to the interest of the community to purify particular effluents, and what are the most economical means of doing so? Is it possible to do so in sufficient degree to restore or maintain the amenities of a river without putting an undue burden upon an industry or upon the local rates? In order to decide such questions, exact and accurate information, often of a very varied nature, is frequently required

In the "Report of the Water Pollution Research Board, 1929–1930",[1] an account is given of several investigations now in progress In order to obtain information of general application, especially concerning the effects on a river of sewage and trade effluents of various kinds and the quantity which can be allowed to enter without unduly retarding the process of self-purification, it was decided several years ago to make a thorough survey of the flora, fauna, and water of a typical river, and their variation throughout the seasons For this purpose the River Tees and its estuary were chosen The present Report gives a short account of the first year's work

The head waters pass within half a mile of the river's source on to a limestone bed, where in the course of only a few yards the pH value rose from 4 to 7 The water remains at about this value until it mixes with the more alkaline sea water in the estuary, throughout which the mixed waters oscillate backwards and forwards with the tides In addition, a circulatory system is set up, the ebb tidal stream being strongest at the surface and the flood tidal stream strongest at depths below one fathom This is very marked when much fresh water enters the estuary Matter suspended in the water of the upper layer has a residual movement seaward, while matter suspended in the lower layers has a residual movement towards the head of the estuary

Above the estuary the river suffers little pollution except from one tributary Series of observations throughout periods of twenty-four hours have been made to determine the changes in the river water and in the quantities of dissolved gases during the day and night Diurnal variations were found in the number of bacteria and dissolved nitrogenous compounds in the water, further investigations are being made with the aim of finding an explanation of this phenomenon

The central portion of the estuary between Stockton and Cargofleet receives the discharge of many industrial effluents and the untreated sewage from 275,000 inhabitants, which gives rise to a heavily polluted zone oscillating up and down the estuary with the tides The effluents undergo oxidation at the expense of the dissolved oxygen in the water, which may fall to below 20 per cent of saturation value during the summer, the minimum found during 1929 being 5 per cent in the central part of the polluted zone Life is almost absent in this portion of the river, where the bottom living animals and plants are also exposed to the greatest changes in salinity, while numerous species occur above it and below Various marine fishes have been found dead and dying at the lower end of this polluted belt, and great numbers of salmon smolt at the upper end as they enter it during their migration to the sea From the results obtained during the first year of the survey, the general changes in the composition of the river water at different times of year, and under different conditions of rainfall and states of the tide, have been ascertained The nature of many effluents has been examined Their poisonous constituents and influence on the water and fauna of the estuary continue to be the subject of investigation, which has proved increasingly fruitful during the second year's work

The Report deals next with the purification of effluent from beet sugar factories By using over again the wash water and by biological filtration of the effluent, this can now be rendered relatively harmless The experiments have demonstrated the conditions under which percolating filters can be operated satisfactorily thoughout a beet sugar campaign for the requisite purification of pulp press liquor, suitably diluted with river water or with effluent from the filters

The parts played by various organisms present in the filters continue to be investigated, with the object of isolating pure strains specially active in decomposing and oxidising the substances present in the effluents It is noteworthy that the work has led to the discovery of new strains of nitrifying bacteria which belong to neither *Nitrosomonas* nor *Nitrococcus*

The changes taking place in the zeolite process of water softening and the treatment of corrosive and plumbo-solvent waters are also the subject of

research Water mains sometimes become so corroded that they burst when under pressure, or deposition of organic and inorganic substances may take place to such an extent as to diminish seriously their water carrying capacity There is a lack of exact information, not only as regards the best treatment of the plumbo solvent waters, but also on the variation of this plumbo solvent character with the composition of the water

For the most economical working of the activated sludge process of sewage disposal, more precise knowledge of the various factors involved is required As the relative importance of the parts played by the bacterial and the physico chemical changes is unknown, experiments are being made with sewage effluent freed from bacteria An investigation is also being carried out on the dissolved colloids and the conditions which affect their quantity and nature

Although much of this varied research is still in the initial stage, it is abundantly clear that it cannot fail to yield many facts of scientific interest as well as of practical importance The work of the Board on the treatment of effluents from beet sugar factories has already provided a solution to an urgent social problem

The Committee appointed in May 1919 by the Ministry of Transport and the Ministry of Agriculture and Fisheries to investigate the question whether tarred roads are harmful to fisheries, has also published a report [2] containing a wealth of experimental results The toxicity towards fish of aqueous extracts from various tars has been investigated, and also the toxicity of their various poisonous constituents, phenol and higher phenols, bases such as ammonia and quinoline, and hydrocarbons such as naphthalene Similar experiments have been made with the drainage from tarred surfaces, which lose much of this toxic property after the first heavy rains have washed out the more soluble substances

The major experiment consisted in passing the rain washings from an area of tarred road into small ponds stocked with trout, through which there was a flow of fresh water These trials proved that undiluted washings from the freshly tarred roads were deadly to fish—unless diluted, for safety, with about ten times their volume of unpolluted water The subsequent drainage from the road was less toxic, but rose again where the surface began to disintegrate Parallel trials were made with rain washings which were stored or allowed to pass through a filter of cut turf, it being known that the phenols constituting tar acids and naphthalene are broken down by the action of bacteria which occur in soil In both cases the treatment was found to reduce the injurious character of the rain washings

As a result of these investigations, mostly carried out between 1920 and 1922, and the experience gained by this Committee, the Ministry of Transport warned all road authorities against the use of unsuitable tars on roads draining directly into streams It cannot be doubted that there has been a diminution in destruction of fish during the last six years The investigations are still proceeding, and include the examination of samples of home produced coal tar preparations which aim at being non-toxic, and so able to replace bitumen without danger to fisheries

Obituary

Lt Col Sir Richard Temple, Bart , C B , C I E

We regret to record the death of Lieutenant Colonel Sir Richard Temple, the distinguished Oriental scholar, which took place on Mar 3, at Territet, Switzerland Sir Richard Temple was born at Allahabad on Oct 15, 1850, and was educated at Harrow and Trinity College, Cambridge He joined the Royal Scots Fusiliers in 1871, and after six years' service in India was transferred to the Indian Army, serving in the 38th Dogras and 1st Gurkhas After a distinguished military and administrative career, in which he served in Afghanistan and Burma, in 1895 he was appointed High Commissioner of the Adamans and Nicobars and superintendent of the Penal Settlement of Port Blair, a post which he held until his retirement in 1904 On his return to England, Temple settled on his family estate in Worcestershire During the War, as chairman of the Worcestershire Territorial Association, he took an active part in the recruiting, organisation, and training of reinforcements, and he also worked hard in connexion with the St John's Ambulance Association, of which he was assistant director, his war services being recognised in 1916 by the award of the C B

Sir Richard Temple was a quick and indefatigable worker A busy official career which would have left most men little leisure only served to afford him opportunities for increasing the range of his knowledge There were few matters connected, however slightly, with Indian culture on which he was not qualified to speak as an expert—history, religion, ethnology, linguistics, numismatics, archæology, or folk lore His census reports for Burma in 1891 and the Andamans and Nicobars for 1901 contain many noteworthy contributions to the folk lore and ethnology of these districts He had, however, long before, taken a recognised place as an authority on folk-lore by his "Legends of the Punjab" (1883–1890) and his notes to Mrs Flora Annie Steel's 'Wideawake Stories" (1884) He had also founded and edited *Punjab Notes and Queries* In Burma he made a special study of the Burmese belief in spirits, revising Burnell's "Devil Worship of the Tuluvas", and publishing his own study of "The Thirty-Nine Nats" He also collaborated with the late E H Man in a work on the languages of the Andamanese, and he elaborated a "Theory of Universal Grammar applied to Savage Languages", a scheme of which the merits have not been fully recognised An equal originality was shown in his studies of the currency systems of

backward peoples, which he maintained gave a key to the understanding of their culture Here again the acuteness of Temple's views has been appreciated by only a few experts

Temple was the author of many contributions to learned periodicals, and his wide range of knowledge made him an ideal editor of the records of early travellers and historians He was responsible for volumes produced by both the Hakluyt Society and the Indian Records series He also inspired others, and his reports as High Commissioner of the Andamans contain valuable notes made by his officers on punitive expeditions and visits of inspection among the, at that time, lesser known Andaman tribes But his greatest service to Indian scholarship was the foundation of the *Indian Antiquary* in 1884, of which he continued to be editor-in chief up to the time of his death, publishing it at his own expense In the mass of material which appeared in its pages, invaluable to the student of Indian culture, Temple leaves a monument which will endure for all time

On his retirement, Temple continued his literary and scientific activity with unabated energy In 1913 he was president of Section H (Anthropology) of the British Association His presidential address on "Anthropology as a Practical Science" was made the starting point in a campaign of which he was the leading spirit in pressing for State aid for anthropological studies This was interrupted only by the War In 1920, when he was a member of council of many learned bodies, he was also appointed director of the Royal Asiatic Society, and in 1928 he was president of the Jubilee Congress of the Folk lore Society Unfortunately, the state of his health after the War obliged him to reside for the greater part of each year in Switzerland, but this had little perceptible effect on the volume of his work He continued to produce innumerable papers and notes based upon the material he had collected in his earlier years At the time of his death, he was also engaged on a series of monographs on Indian Muslim saints, in alphabetical order, of which two sections, from A to H, are complete His mental vigour, his memory, and his mastery of detail were unimpaired to the end

PROF J S DUNKERLY

THE untimely death in his fiftieth year of Prof John Samuel Dunkerly, of the University of Manchester, inflicts a distinct loss upon British zoological science Evading publicity, and having to his credit only a comparatively small volume of published research work, he aroused full appreciation of his capabilities only in the minds of the comparatively few with whom he worked in close intimacy

Dunkerly owed the main part of his zoological training to the late Prof E A Minchin, from whom he inherited alike his most conspicuous strengths and weaknesses as an investigator—fastidious care in matters of technique and accuracy of observation, combined with a modest diffidence in his own powers which was apt to result in hesitancy to commit himself to the ready acceptance of conclusions, either his own or those of others His output of published research work suffered disastrous interference by the War, in which he did splendid service as a combatant officer—first in the Cameronians, then in the Machine Gun Corps, and finally in the Royal Air Force until shot down during the closing year of the War The wound then received resulted in severe septicaemia which left him permanently crippled and subject from time to time to attacks of severe illness and much suffering Those who were privileged to work with Dunkerly during his later years developed a profound admiration for the gay and light hearted courage with which he faced his troubles, never losing heart until the very end

Dunkerly's published researches, comparatively small in amount, deal mainly with obscure Protozoa The Flagellata took first place in his interest during earlier years, and he devoted much time to the investigation of Choanoflagellates and of the protozoan parasites infesting the alimentary canals of insects Latterly his interests centred rather on the Myxosporidia He made the first study of *Agarella*, a common parasite of the testis tubules of *Lepidosiren*, and upon this work he eventually based his most important contribution to the literature of protozoology—his study of the development and relationships of the Myxosporidia—published in the *Quarterly Journal of Microscopical Science* for 1925 In this interesting and suggestive paper, attention is directed to the parallelism in structure between the Myxosporidian, in which the amœbula—the essential reproductive element—is enclosed in complicated multinucleate arrangements of an accessory kind, the whole forming the characteristic and complex 'spore', and the Metazoon, in which the reproductive material or gonad is contained within the multicellular soma There is, of course, no suggestion of a Myxosporidian ancestry for the Metazoa the thesis supported by Dunkerly is simply the very interesting one that "the origin of the Metazoan type was, as in Myxosporidia, a development of a body or soma, originally for protection of the real individual organism represented by the germ or gonad"

From 1911 until 1926 Dunkerly held the post of lecturer on zoology in the University of Glasgow, where his efforts met with high appreciation, and where he showed himself to be a teacher of unusual gifts and power of arousing interest on the part of his pupils In 1926 he was appointed to the Beyer chair of zoology at the University of Manchester on the retirement of Prof S J Hickson

During the closing months of 1930 Dunkerly seemed to be at last restored to a fair measure of health and strength He had completed the personnel of his junior staff and was looking forward, with their loyal and enthusiastic help, to being able to run his University department at the highest possible level of efficiency It was shortly after Christmas that there became apparent the first foreshadowings of the approaching tragedy, in the form of symptoms pointing to some obscure infection of the pons region of the brain

News and Views.

Dr Walter Rosenhain, who has been superintendent of the Metallurgy Department of the National Physical Laboratory for the past twenty five years, is leaving the Laboratory in June to take up consulting work As a skilled physicist and microscopist, as well as metallurgist and engineer, Dr Rosenhain has added greatly to the instrumental means at the disposal of the metallurgist for the prosecution of his researches, while his close acquaintance with modern developments in physics has enabled him to bring the latest knowledge of atomic structure to bear upon the specific problems of the metallurgist A large amount of original research is associated with his name especially in relation to the physical structure of metals and alloys and the mechanism of failure under stress Before and during the War he was largely responsible for the development of light alloys as used in aircraft construction and for parts of explosion engines In this connexion, he investigated the mechanism of age hardening, and introduced improved methods of casting He gave much attention to the production of metals in a high state of purity, for example, chromium, manganese beryllium, and iron—the last in particular, for the purpose of the researches on iron alloys carried out for the Alloys of Iron Research Committee of the Institution of Mechanical Engineers Last year he was awarded the Bessemer Gold Medal of the Iron and Steel Institute In connexion with his metallurgical work it was necessary to give much time to the study of special refractories, and many improvements in laboratory furnaces and in metallurgical processes dependent on the use of better refractory materials are due to his initiative Dr Rosenhain has acquired an international reputation as a metallurgist

Mr C Davies Sherborn has had the degree of D Sc *honoris causa* conferred upon him by the University of Oxford in recognition of his work on the "Index Animalium", the final parts of which are now ready for, if not actually passing through, the press It is just forty years since Dr Sherborn began his self imposed task of providing an index to the scientific names that have been given to animals by systematic zoologists since the time of Linnæus The first part, containing the names published between 1758 and 1800, was issued by the Cambridge University Press, as a volume of 1254 pages, in 1902 The publication of the second section, bringing the record down to the year 1850, was begun by the Trustees of the British Museum in 1922, and twenty four parts have been issued since that time, containing in all 6118 pages and carrying the index to midway through the letter 'S' The total number of names so far indexed amounts to more than 400,000 These figures give some impression of the magnitude of the task When it is added that the names had to be collected by laboriously searching the files of innumerable scientific periodicals and separate works, many of them rare and difficult to obtain, and that questions of authorship and date of publication often involved prolonged and difficult researches, it seems almost incredible that the task should have been accomplished single-handed Every one with experience of bibliographical work will appreciate the courage required to plan such an undertaking, and the tireless industry and self sacrificing devotion that could alone carry it to completion Zoologists of the greatest eminence all over the world have borne testimony to the value of Sherborn's work, and letters expressing the most unqualified appreciation have recently been received from Stockholm, Copenhagen, Berlin, Frankfort, Paris, New York, and Washington His many friends in Great Britain and abroad will learn with pleasure of the high, but abundantly merited, distinction that has been conferred upon him

The following were elected fellows of the Royal Society of Edinburgh at a meeting held on Mar 2 W A Bain, assistant in the department of physiology of the University of Edinburgh, W M Baird, fellow and past president of the Faculty of Surveyors of Scotland, Dr T P Black, head of mathematics department, Trinity Academy, Leith, Prof J A Carroll, department of natural philosophy, University of Aberdeen, Dr J M Cowan, assistant keeper, Royal Botanic Garden, Edinburgh, J Crichton, assistant superintendent, Meteorological Office, Edinburgh, Dr Shepherd Dawson, principal lecturer on psychology, Training College, Glasgow, Philip Eggleton, lecturer in biochemistry in the department of physiology, University of Edinburgh, Dr W R D Fairbairn, consultant physician and lecturer in psychology, University of Edinburgh, Robert Grant, publisher (Oliver and Boyd, Edinburgh, Gurney and Jackson, London), Dr J R Greig, director, The Moredun Institute Animal Diseases Research Association, Gilmerton, J Henderson, manager and secretary, Edinburgh Assurance Co, Ltd, Prof T Johnson, Tomeg, Hillview, Corstorphine, Dr J du P Langrishe, lecturer in public health, University of Edinburgh, N M H Lightfoot, lecturer in mathematics, Heriot Watt College, Edinburgh, Dr W J McCallien, lecturer in geology, University of Glasgow, Dr W H McCrea, lecturer in mathematics, University of Edinburgh, Dr J B McDougall, medical director, British Legion Village, Preston Hall, Kent, J H. Mason, veterinary research worker, London, F C Mears, architect, 3 Forres Street, Edinburgh, Dr A. Nelson, lecturer in agricultural botany, University of Edinburgh, Dr J Phemister, senior geologist, H.M Geological Survey of Scotland, W Robb, director of research, Scottish Society of Research in Plant Breeding, Corstorphine, Midlothian, H S Ruse, lecturer in mathematics, University of Edinburgh, J J M Shaw, lecturer in surgery and clinical surgery, University of Edinburgh, J F Shearer, lecturer in natural philosophy, University of Glasgow, G A Steven, assistant naturalist at the Plymouth Laboratory, Marine Biological Association of the United Kingdom, Dr C P Stewart, lecturer in general biochemistry, University of Edinburgh, D Cleghorn Thomson, Scottish regional director, British Broadcasting Corporation, Dr W J Walker, research

chemist, H.M. Fuel Research Station, East Greenwich, London, Prof John Walton, department of botany, University of Glasgow, Right Hon T B Whitson, Lord Provost of the City of Edinburgh, Dr J Wishart, statistician, Rothamsted Experimental Station, Herts

ON Mar 2, the House of Commons passed, by a large majority, the second reading of a bill to regulate the protection of grey seals in British waters At present the grey seal is protected during the greater part of its breeding season, but its protection comes up for review annually and depends for its continuance on the Expiring Laws (Continuance) Bill If the new Bill becomes law, protection will be guaranteed, with this proviso, that the Minister of Agriculture and Fisheries for England and the Secretary of State for Scotland may withdraw protection during the breeding season, either wholly in any breeding period or during part of the period, or in any specified area during the whole or part of the breeding season The statements made in the House by the official supporters of the Bill were admirably moderate and we have no doubt that the Ministers concerned will consult opinions other than those of interested parties before deciding upon any relaxation of the present protection Other statements made in support of the Bill were less admirable Sir Robert Hamilton cited against the grey seal the case of a gentleman who had shot about a thousand seals in re establishing a salmon fishery But surely the seal in question was the common seal, a coast loving and estuarine species, the habits and distribution and frequency of which are very different from those of the seal which Sir Robert Hamilton was attacking We direct attention to this false argument because we have on other occasions noted a tendency to drag in against the grey seal irrelevant accusations based on the well known depredations of the common seal

ON Mar 7, and again more strongly during the early morning of Mar 8, severe earthquakes were felt over a large part of the Balkan peninsula causing much damage and some loss of life Many buildings have been destroyed at Valandovi, Strumitza, and Demirkapu, and there has been some, if perhaps less, damage at places so far apart as Sofia, Kustendil, Nevrokop, Gorna Jumaya, and Svetivratch, that is, within an area about 100 miles in diameter The shock was felt at Adrianople, Nish, and Salonika, and thus the disturbed area, as indicated by the early reports, must have been at least 350 miles long from east to west, extending in the latter direction to the neighbourhood of Skutari, and about 200 miles wide The epicentre probably lies about 100 miles to the north of Salonika, and close to one of the most active zones (that of Rilski Monastir) in the central portion of the peninsula One feature of the earthquakes that may prove to be of interest is their possible connexion with the Bulgarian earthquakes of three years before A brief report on these earthquakes by Prof G Bontcheff has recently appeared in the *Matériaux pour les Études des Calamités* (No 22, pp 98-116, 1930) The epicentre of the earthquake of April 14, 1928, lay near Tchirpan, that of the earthquake of April 18 near Plovdiv (or Philippopolis), about 25 miles to the west In the recent earthquake, the seat of activity was transferred about 80 miles still farther in the same direction

ON Mar 4, Sir William Bragg gave a lecture on Michael Faraday which formed one of the series of National Lectures arranged by the British Broadcasting Corporation As Fullerian professor of chemistry, Sir William spoke as Faraday's successor in the laboratories and lecture room of the Royal Institution, and a special interest invested his account of the great experimental philosopher's life and work in view of the forthcoming celebration of the most notable of his discoveries, that of electro-magnetic induction Aug 29 1831, is the date of the first successful experiment in the induction of electric currents, and in this the centenary year some time was naturally given to an explanation of the nature and significance of the electrical researches, but within the limits of the time set for his talk, Sir William also gave a very interesting account of the man himself, of his early life as a bookseller's apprentice, his introduction to Davy and to scientific work, his lovable character, and of the vision which filled his mind and directed and informed all his experimental inquiries—that of the essential unity of Nature and of the relations to be sought between its different manifestations Faraday could have had no more sympathetic interpreter, and many who listened must have caught something of the personal magnetism which gave to his own lectures their charm and drew Victorian audiences to the Royal Institution

Two series of Faraday s electrical experiments were described in some detail first, those on the induction of electric currents, leading up to the recognition, the real 'discovery' of electro magnetic induction, that the induced current was only obtained at 'make' and 'break' of the inducing voltaic circuit, followed by the induction of electric currents in a closed conducting circuit by mere approximation of a permanent magnet The second set of experiments were electrostatic, and culminated in the famous one in which he constructed a great 12 ft cube, and by standing inside it with an electroscope proved that an electric charge resides on the outside of a conductor, or rather, as he saw it, exists as a state of tension in the medium which surrounds it Sir William concluded his talk with a brief but most interesting reference to Faraday's religious life He belonged to a small and little known sect, the Sandemanians, the tenets of which he held faithfully throughout his life Although it is a natural impulse to seek some connexion between his science and his religion, Faraday himself apparently regarded them as two separate and distinct things, and his reserve in religious matters was such that we are left with little upon which to base an opinion as to his personal attitude towards them

IN his Friday evening discourse on Mar 6 at the Royal Institution on "Ozone in the Upper Atmosphere and its Relation to Meteorology", Dr G M B

Dobson described the chief results which have been obtained from researches on the ozone in the upper atmosphere carried out in many parts of the world during the last five years The methods were described whereby the amount of ozone can now be accurately measured with ease in a few minutes The ozone, which is situated at a height of some 50 km above sea level, has a well marked annual variation which is different in different parts of the world At all places outside the tropics, there is a maximum in the spring and a minimum in the autumn, the range being greatest in high latitudes and least in low latitudes In temperate regions there are also large changes from day to day which are closely related to the weather conditions, cyclones and anti cyclones each having their own characteristic distribution of ozone It is not at present understood how this relation is caused, since the ozone is much higher in the atmosphere than most of the processes affecting the weather Neither is it known at present with certainty how the ozone is formed The ozone in the upper atmosphere is responsible for shielding the earth from intense ultra violet radiation from the sun, which would cause serious effects if it reached the surface It further causes the upper atmosphere at a height of 40 50 km to be at a temperature in the neighbourhood of the normal boiling point of water This, in its turn gives rise to the zones of abnormal audibility of sound from large explosions at a distance of some hundred miles from the explosion itself

THE British Optical Instruments Manufacturers' Association has issued an attractive booklet as a souvenir of the exhibit at the recent British Industries Fair It gives a summary of some of the outstanding advances in optical instruments since the War, and includes an interesting section illustrating the multifarious uses of scientific instruments in various industrial operations The industry is entitled to take a real pride in many of these recent achievements, and although no names are mentioned in the booklet, we find well deserved references to the instruments and especially the interferometers of Messrs Adam Hilger, Ltd , the $f/2$ anastigmat lenses of Messrs Taylor, Taylor and Hobson, Ltd , the fine-adjustment mechanisms for the ultra violet microscopes of Messrs R and J Beck, Ltd , the wide angle binoculars of Messrs Ross, Ltd , and productions of other firms too numerous to mention here It is certainly true to say that such advances have only been made possible by the most strenuous of efforts As the president of the Association said in 1925, in reference to the post War slump, "Then came the time of readjustment, of a dearth of orders that bordered on starvation , but the trade drew the belt tighter and tighter, hung on, and responded to that severe stimulus by an effort of experiment and development which is without precedent in its history" This effort still continues, and if, as we understand, it is now resulting in a rising level of activity and prosperity in the industry, then success will be well deserved

THE optical trade has certainly enjoyed a measure of protection, but the opportunity has been taken to strengthen the foundations of scientific control, the activities of the British Scientific Instruments Research Association, the National Physical Laboratory, the Technical Optics Department at the Imperial College of Science and Technology, and the Optical Society have created an entirely new atmosphere in which progress is appreciated at its true value The achievements are mainly, however, brilliant individual performances , unfortunately perhaps, the kind of competition that must be faced is a very large co operation of brains, capital, and labour organised on a big scale With the utmost pride in British firms and their unbeaten products, we must not forget the fact that big things are being done elsewhere Planetariums, stereo planigraphs, and the like, are no mere rumours Even if sometimes these 'big noises' are more useful as advertisements than as commercial ventures, the trade cannot afford to forget the advertising power of spectacular things, or that two designers of experience, working whole heartedly together, will usually achieve something much better than is possible to either working alone

IT is announced in *Chemistry and Industry* for Feb 20 that the International Atomic Weights Commission will meet for the first time since the War In the issue of Jan 30 it is stated that the Federal Council for Chemistry, in view of the progress made in ensuring the truly international character of the Union Internationale de Chimie, has decided to dissolve the existing committees on the chemical elements and to appoint a new international committee This is to consist of G P Baxter (United States), O Hönigschmid (Munich), P Lebeau (Paris), R J Meyer (Berlin), and Mme Curie Prof G Urbain has been elected honorary president of the committee The committee is charged with the duty of preparing an annual international table of atomic weights New committees on isotopes and radio active elements are in course of formation A letter from Dr F W Aston, which appeared in NATURE for Dec 20, 1930, is of interest in this connexion The 'unit' of atomic weights has for some time been oxygen (16), originally introduced because the values of Stas were based more or less directly on this standard Very few of the newer values have, as a matter of fact, been referable directly to oxygen, and Dr Aston has now directed attention to the further difficulty introduced by the recent discovery that oxygen is not a simple element but a mixture of isotopes The use of a mixed element as the standard of atomic weights would seem undesirable

BARON GIAN ALBERTO BLANC, professor of geochemistry in the University of Rome, has, during the past twelve years, successfully attacked the problem of extracting alumina and potash salts from leucite, a mineral consisting of a silicate of alumina and potash which exists in very considerable amounts in the volcanic rocks of central Italy and hitherto considered worthless In the course of a public lecture before the Institution of Chemical Engineers at the Institution of Civil Engineers on Mar 5, Baron Blanc said that the first problem with which he was confronted was to find a practical means of separating

the alumina and the potash from the silica This was solved by a new method of attack of the silicate by acids, which allowed an easy and complete elimination of the colloidal silica from the solution Some years ago, Prof J W Hinchley directed the attention of the English technical world to this process, and it is at present used in England by Peter Spence and Sons for the manufacture of alum by the treatment of leucite with sulphuric acid The problem of separating the salts obtained by the acid treatment, so as to produce the potash as a fertiliser and the alumina for metallurgical and chemical work, was then attacked Finally, by thermal decomposition of the aluminium salt, a new type of chemically active aluminium oxide was obtained, which has proved much more suitable for the production of aluminium than the aluminium oxide obtained through calcination of the hydrate One of the characteristic features of the Blanc process is that it requires only a very limited amount of fuel A large plant for the treatment of one hundred metric tons of leucite per day is now being completed at Aurelia, near Rome, and will soon be working The supply of leucite of which Italy can dispose is calculated in milliards of tons

At the close of the annual corporate meeting of the Institution of Chemical Engineers held on Mar 6, the retiring president, Mr Arthur J Reavell, opened a discussion on the education and training of the chemical engineer After referring to the pamphlet on this subject issued by the Institution in 1925, he expressed great dissatisfaction with the present method by which a student is now usually trained in chemical engineering, by first taking a degree course in chemistry The result is an ill balanced course, very deficient in engineering training He thinks that engineering is the most important subject and should be taken first A well balanced training would consist of two years' work with the engineering, physics, and chemistry students, utilising the existing organisations in these subjects, followed by two years' work in the chemical engineering laboratories, and the final attainment of a degree in that subject Such laboratories, however, should have far more comprehensive equipment than they have at present

Sir Frederic Nathan explained that the pamphlet on the "Training of the Chemical Engineer" published by the Institution in 1925 was produced by the assistance and approval of industrialists throughout Great Britain Since that time, two schools in London—a third has just been started—have been giving instruction on the lines of this pamphlet There is no difficulty in obtaining employment for such men, but Sir Frederic believes that students should be entered for chemical engineering right from the beginning of their university training Sir Robert Robertson did not agree with Mr Reavell he thinks that the training should be essentially one of chemistry, to be followed by a 'top dressing' of engineering and chemical engineering, and he was supported by Mr McKillop (British Dyestuffs Corporation) Mr Heron Rogers is of opinion that a student of good calibre can be trained to be both a good chemist and a good engineer, and become an expert in these subjects and also in chemical engineering After Mr Rintoul had emphasised the fact that a university cannot produce chemical engineers, but that works training is essential, Dr Dunstan (Anglo Persian Oil Co) explained how his company is training and utilising university graduates as chemical engineers Mr C S Garland (Steatite Products, Ltd) emphasised the measure of agreement among the speakers with a demand for a special branch of university training so that the student may enter as a chemical engineering student and take a well-balanced course involving all those subjects necessary to the profession of a chemical engineer The discussion was closed by Mr Tizard, who pointed out that the problem is a special case of the adaptation of university training to industry and industry to university training He sees no reason why chemical engineering should not be accorded a similar organisation at the universities as electrical engineering and mechanical engineering

At the fifty third annual general meeting of the Institute of Chemistry, held on Mar 2 at the Institute, Russell Square, the president, Dr G C Clayton, presented the Meldola Medal to Dr R P Linstead, of Imperial College of Science, and the Sir Edward Frankland Medal and Prize, for registered students, to Mr G Broughton, of the Royal Technical College, Salford In submitting the report of the council, the president remarked on the increase in membership, which now comprises over 5850 fellows and associates The financial position is also satisfactory The legal and parliamentary committee has been more than unusually active, having dealt with such matters as chemical patents, service agreements for chemists, the Dyestuffs (Import Regulation) Act, the regulations dealing with methylated spirits, and a proposal to present a petition to H M the King in Council for a supplemental charter, in order to acquire for the fellows and associates the right to use the title 'Chartered Chemist' The Council is of opinion that it is desirable that members of the Institute should acquire this title, in order to distinguish them from pharmaceutical chemists The meeting considered the adoption of the petition for the supplemental charter, but, although on a division supported by a decided majority, it was referred to a postal vote

An experimental room has been set up at the London School of Hygiene and Tropical Medicine in which it is possible to reproduce by means of an air-conditioning plant varied climatic conditions and any temperature, humidity, or air movement which may occur in factories or mines Experimental subjects rest or work under the conditions to be investigated, and by observation of the pulse, body temperature, skin temperature, loss of weight due to sweating, and expenditure of energy by measuring the air breathed and oxygen used, it is possible to study the effect of such air conditions on the human body Formerly the carbon dioxide percentage in the air was regarded as the best index of good or bad ventilation, until Sir Leonard Hill proved conclusively that it is not the percentage of carbon dioxide in a badly ventilated room which causes the sensation of discomfort and stuffiness, but the physical properties

of the air and their influence on the temperature re gulating mechanism of the body Sir Leonard Hill's kata thermometer assesses the cooling effect of these environmental factors in one measurement, namely, the rate of cooling, or cooling power It has been shown that certain cooling powers are suitable for sedentary work, or light or heavy manual work, and thus, so far as possible the ventilation and heating systems in buildings or factories or mines should ensure that these desirable cooling powers are maintained Investigations in mines by Dr H M Vernon, of the Industrial Health Research Board show that working capacity declines and accidents increase in frequency if the cooling power of the en vironment is too low and throws too great a strain on the body

The Council of the British Association has resolved to nominate Sir Alfred Ewing lately Principal and Vice Chancellor of the University of Edinburgh, as president of the Association for the year 1932

At the annual corporate meeting of the Institution of Chemical Engineers held in London on Mar 6, the Osborne Reynolds Medal (1930) was presented to the retiring president Mr Arthur J Reavell, by Sir Alexander Gibb The Moulton Medal (gold) was presented to Mr A T King for his paper on the "Treatment of Suint Liquors" The Junior Moulton Medal (silver) was awarded to Mr L W Blundell for his paper on the "Manufacture of Hydrogen Peroxide"

We have received a copy of the *Engineer* Directory and Buyers' Guide for 1931, which, besides classified lists of engineering firms advertising in that journal, with their telephone numbers, telegraphic addresses and the codes used, contains a list of the technical headings used in the directory, with translations in French, German, Italian, and Spanish A list is also given of the British Standard Specifications and Reports The directory is published annually and is issued free of charge

Applications are invited for the following ap pointments on or before the dates mentioned — A lecturer in natural and agricultural sciences at Harrison College, Barbados—C A, The Secretary, Board of Education, Whitehall, S W 1 Scottish candidates to C A, The Secretary, Scottish Educa tion Department, Whitehall, S W 1 (Mar 30) A lecturer in geography at St Gabriel's Training College, Camberwell—The Principal, St Gabriel's Training College, Camberwell (Mar 30) A superintendent of the Metallurgy Department of the National Physical Laboratory—The Director, National Physical Labora tory, Teddington (Mar 31) A lecturer in geography at the University College of Swansea—The Registrar, University College, Singleton Park, Swansea (April 11) A professor of brewing in the University of Birmingham—The Secretary, The University, Birming ham (April 20) A lecturer in natural philosophy in the University of St Andrews — The Secretary, University of St Andrews, St Andrews (April 22) An assistant lecturer in metallurgy at the County Tech nical College, Wednesbury—The Director of Educa tion, County Education Offices, Stafford (April 23)

Our Astronomical Column

The Elongation of Eros – The *Daily Science News Bulletin* for Feb 6 issued by Science Service Washing ton, D C, contains some details of the elongation of Eros, they are based on a telegram from Johannes burg, transmitted through the I A U Bureau, Copen hagen, and on observations by Mr Leon Campbell at Harvard It is concluded that the long diameter of Eros is 25 to 29 miles, and the axis of rotation 8 to 10 miles The long diameter must be in the equatorial plane, and the earth must have been in this plane at the time when the light variation was at a maximum, about last December, the slight dissymmetry between the two maxima would be explained by difference of albedo of the opposite faces The exact time of rotation of Eros is given as $5^h\ 16^m\ 12\ 94^s$, but there are two maxima and two minima in this period *Bulletin* 187 of Kwasan Observatory, Kyoto, gives $2^h\ 38^m\ 4\ 546^s$ for the half period

The observations at Johannesburg were made by Dr W H van den Bos and Mr W S Finsen, using the 26 inch refractor of the Union Observatory The explanation of the light variation by the departure of Eros from a spherical form is antecedently more probable than by the hypothesis of variable albedo of different portions of its surface, the variations of albedo would have to be extremely great to pro duce so marked a change of light

The Variable Star with the Shortest Known Period *Bull* No 214 of the Astronomical Institute of the Netherlands contains an account of the discovery of this variable, the position of which for 1900 is R A $8^h\ 19^m\ 38^s$, S Decl 18° 44 9′ Mr H van Gent, of Leyden Observatory, who is now at the Union Observa tory, Johannesburg, detected the light variation by comparing two plates in the blink microscope Several earlier plates containing the star had been sent to Leyden and these have been examined by Mr A J Wesselink and Prof E Hertzsprung The period is 0 069746 days, or 100 4 minutes A difficulty arises, since the magnitude is about 14 to 15, and an exposure of some thirty minutes is needed to show it clearly when near minimum, this is such a large fraction of the whole period that photography is unsuitable for obtaining the light curve Visual observations have now been made at Johannesburg The light curve is drawn as a simple sine curve, the light range being one magnitude

Photographic Photometry of the Magellanic Clouds —*Bull Astr Soc Netherlands*, vol 6, No 209, con tains a study of the Magellanic Clouds by G van Herk, of the Lembang Observatory The method was that of extra focal images, the size and black ness of the images being measured The images of the cloud are compared with those of stars of known magnitude

Diagrams are given, showing the isophotic lines in the two clouds Each has an elongated nuclear region of greatest brightness not far from the centre The large cloud has a second, less bright nucleus, not far within the northern border of the cloud The isophotic lines embrace each nucleus with an approach to regularity, and an ill defined ligament connects the two nuclear regions The structure of the small cloud is much simpler and more regular

The integrated light of the large cloud is found to be 1 2 mag, of the small cloud 2 8 mag Hubble had found 0 5 mag for the large cloud, and Paraskevo poulos 1 8 for the small

Research Items

Bushman Paintings in Eastern Cape Province.—Mr. John Hewitt and Father P. Stapleton, S.J., in vol. 4 of the *Records of the Albany Museum*, Grahamstown, South Africa, describe paintings and artefacts discovered in rock shelters near Cala. Rock paintings in this area are very numerous, but have never been described in detail. The locality of the present investigation is Tembuland, which is east of the Drakensberg and south of the Stormberg. At Rebels' Kloof a great number of implements were found and the rocks were covered with paintings, some of fine technique but in poor preservation. In one case there were some very remarkable human figures with attenuated limbs in white. Other paintings of apparently the same age showed carnivores, elands, etc. Another series of human and animal figures was entirely in black, including a well drawn black elephant. A rock shelter on the other side of the river contained a fine series covering nine or ten yards, with excellent decorative effect. The biggest figure is an eland in dark red and white. Yellow and white paintings here seem to be the most recent. Two human figures in chocolate, and faint, may be older. Not far distant was a hunting group in white. The hunter is approaching a herd of reboks, mostly at rest, with a 'gargantuan stride.' High up on the krantz, and inaccessible, near beautiful elands, were two human figures, remarkable for the fact that they wear skin capes reaching to the knees, giving the figures quite a European appearance. The faces are white broadly bordered with chocolate bands, which is also the colour of the legs. As regards the artefacts, the major stone industry belongs to a group included in the Smithfield cultures. The pottery of Rebels' Kloof shows two distinct industries.

Uterine Cycle in the Marsupial *Bettongia*.—The species examined by Prof. T. Thomson Flynn, *B. cuniculus*, is one of the 'rat kangaroos' of Tasmania, and the investigation adds usefully to the known facts concerning the reproductive phenomena of the diprotodont marsupials (*Proc. Linn. Soc. N.S. Wales*, vol. 55, 1930, p. 506). The species has several breeding seasons in the year, and there may actually be an overlapping of the gestatory and lactatory periods. Only one young is born at a time, but there are four teats in the pouch, so that three are unoccupied at a time, a condition the reverse of that in another marsupial group where the young exceed the teats in number. Hill and O'Donoghue have pointed out that marsupials show a progressive reduction in the number of teats present in the pouch, but there is also a progressive reduction in the number of the young, and this reduction has reached its limit in cases such as the present where reduction in number of young has proceeded in advance of teat reduction. Pregnancy is unilateral, and in normal circumstances occurs alternately in each uterus; but when one uterus is pregnant the other enters into and remains in a state of pseudo-pregnancy, which persists until parturition. In view of the likelihood that the ancestral marsupial was a placental mammal, it is interesting to find that this specialised form has only a small allantois, with no allantoic placenta; but the nutrition, respiration, and elimination of waste products of the fœtus are efficiently carried out by a yolk sac placenta.

Hydromedusæ in the North Sea and Channel.—Dr. P. L. Kramp, in "Hydromedusæ collected in the South-western Part of the North Sea and in the Eastern Part of the Channel in 1903–1914" (*Mémoires du Musée Royal d'Histoire Naturelle de Belgique*, No. 45, 1930), describes the Hydromedusæ from those parts of the North Sea and Channel which were allotted to Belgium as its share in the International Plankton Research. The region is limited to the east by a line from the mouth of the river Schelde to Lowestoft, and to the west by a curved line from Fécamp to Newhaven. Most of the material was collected during the quarterly cruises (February, May, August, and November) at a number of fixed stations, supplementary collections being made in other localities and in other seasons. The rough results have already been published in the *International Bulletin*, but, so far as the medusæ are concerned, only a small part of the material was submitted to specialists. Twenty-nine species are now recorded, one of which is new to science. Five sections are recognised in the area investigated: the first in the eastern part of the Channel, the third in the shallow water along the North Sea coasts of France and Belgium, the second in the Straits of Dover, being a transition area between two and three; the fourth, the mid-water region in the North Sea between the coasts of France, Belgium and England, which is a mixture of indigenous forms and species from the Channel; and the fifth, the English coastal region from Dover to Lowestoft, which is like the fourth but less prolific. Conclusions as to the influence of 'Channel water' on the presence of medusæ show that indigenous North Sea species are particularly abundant there when there is little Channel water, and those few medusæ which come from the Channel are almost wholly found in the North Sea sections when the 35 per mille isohaline has a particularly extensive distribution. The new species *Trissocoma brownei* is of special interest. It was first observed by E. T. Browne—in the Channel and at the south-west coast of Ireland—who realised that it was a new species. Dr. Kramp has now found it in fair abundance in his fourth section in two localities between Zeebrugge and Orford Ness, and placed it in the new genus *Trissocoma*, having its natural position between *Cosmetira* and *Mitrocoma*.

Respiration in Higher Plants.—The *Proceedings* of the Seventeenth Indian Science Congress (Calcutta: Asiatic Society of Bengal), held at Allahabad in 1930, contains the presidential address to the Botany Section delivered by Prof. P. Parija. This deals chiefly with the respiration of cherry laurel leaves in air, in nitrogen, and in mixtures of oxygen and nitrogen, and with the interpretation of the results. In partially starved leaves, the effect of nitrogen was to increase slightly the respiration rate, and then, on returning the leaves to air, a considerable increase in carbon dioxide production was observed, the so-called 'after effect.' In nitrogen (or anaerobic) respiration two atoms of carbon are assumed to accumulate as intermediates to every carbon atom appearing as carbon dioxide. If, on admitting oxygen, all the intermediate substances were oxidised to carbon dioxide, the maximum increase of carbon dioxide production in the 'after effect' should therefore be twice the nitrogen respiration, and this is, in fact, the case after long periods (48 hours) of respiration in nitrogen. After shorter periods of two to thirty hours in nitrogen, however, the 'after effect' is only of the order of 1.1 times the respiration in nitrogen, and it is assumed, in agreement with other evidence, that the difference between the theoretical value of 2.0 and the value given is due to the oxidative building up of the remainder of the intermediates. Prolonged exposure to nitrogen is supposed to inactivate the mechanism which brings about the latter method of disposal. On exposing the leaves to different mixtures of oxygen and nitrogen, it is found that there is a minimum production of carbon dioxide when the

mixture contains 5 per cent of oxygen, and maxima in pure nitrogen and in 33 per cent of oxygen The 'after effect' is only observed when the proportion of oxygen is below 5 per cent, although an increase in carbon dioxide production of a different type is observed when the proportion of oxygen is greater than that in air

Oxidation and Reduction in Bacteria—The influence of various conditions on acetic acid formation by *B pasteurianum* has been further studied by Hiroshi Tamiya and Kiyoshi Tanaka (*Acta Phytochimica*, **5**, 167), with special reference to the suggestion that quinone may replace oxygen as a hydrogen acceptor in this type of fermentation They find that carbon monoxide is wholly without influence on the production of acid in the presence of quinone, but greatly reduces it in the presence of oxygen Toluol also delays the fermentation in the presence of oxygen, but influences the reaction only slightly in the presence of quinone or methylene blue In the acetic acid bacteria, the indophenol reaction for oxidase is also reduced by carbon monoxide and toluol, although the latter was found to have no effect on the action of a *Lactarius* extract The explanation given is that the normal function of cytochrome is disturbed by quinone and toluol, and it is concluded that the results agree with the theory that cytochrome acts as a regulator of oxygen pressure in this type of oxygen fermentation, as well as in the oxygen respiration of other plants and animals The same publication (p 119) also contains results by these authors and Tatsutaro Hida on the reduction of methylene blue by acetic acid bacteria (as an intracellular enzyme), by liver extract (as a free dehydrase), and various chemical agents (pyruvic acid and aceto acetic ester) In all cases light is found to accelerate the reduction, a photochemical activation of methylene blue molecules being postulated as the cause Carbon monoxide has no influence on the purely chemical reduction nor on the action of liver extract, but it markedly retards the action of *B pasteurianum* Quinone slows down all three types of action

Bituminous Sandstone, Vernal, Utah—Appropriately named "Asphalt Ridge", there occurs a series of low discontinuous hogsbacks of bituminous sandstone, south west of Vernal, Utah, U S A, which have recently been the subject of investigation by Mr E M Spieker (*U S Geo Sur Bull* 822 C) Most of the sandstone is of the Eocene age, and analyses show that the bitumen content ranges from 8 to 15 per cent by weight Mechanical analyses were conducted to determine the various grade sizes and proportions of such grades present in the sand, the average of the results given shows that the rock is of medium grade The density varies from 1 99 to 2 03 The specific gravity of the sand as extracted is about 2 63, slightly less than that of pure quartz Porosities are also variable, between 29 5 and 38 per cent Apparently some samples gave exceptionally high porosity values, 47 to 49 per cent it is pointed out that the usual pore space of an aggregate of identical spheres is 47 64 per cent, but on the whole the evidence does not suggest that this particular sandstone is composed of markedly rounded grains, so that these high values are not characteristic It is gratifying to note that so much attention has been given to mechanical and textural composition of these rocks, as frequently these vital properties to impregnation are passed over sketchily in favour of fuller description of the bitumen It is anticipated that mining of this bituminous sandstone can be carried back some 1½ miles from outcrop, and thus over the area it is possible to estimate resources of some 1,970,000,000 tons of impregnated rock The sandstone has already been successfully used for street paving in Vernal It is hoped to use the bitumen as a source of motor fuel by hydrogenation processes, but it is not clear whether the rock lends itself to easy and cheap extraction, or by what method this will be accomplished on a commercial scale

Red Rain in Victoria—Mr Frederick Chapman, Palæontologist of the Australian Commonwealth, has continued his observations on red rain in south eastern Australia which he began in conjunction with H J Grayson in 1903 We are unable to print Mr Chapman's communication in full, but his observations are summarised below On the night of Dec 31, 1927, after a strong northerly wind had carried thick clouds of dust over Victoria and blown the finer particles southward over Bass Strait, there were heavy but irregularly distributed falls of red rain Mr Chapman estimated the amount deposited in Balwyn, a suburb 8 miles east of Melbourne, at 51¾ tons per square mile the Commonwealth Meteorologist, Mr H A Hunt, estimated the deposit at Elsternwick at 24 tons per square mile The red dust on this occasion was exceptionally sticky, as the innumerable diatoms—*Nitzschia* and *Cocconeis*—still contained their endochrome The red stains on leaves and flowers in the gardens were retained for days and even weeks The impressions on glass indicate that each raindrop was coated by a thin film of the dust On Nov 3, 1920, after a northerly gale, showers of red rain fell at 7 P M and after 9 P M The amount of the red sediment collected in a vessel in Mr Chapman's garden indicated a fall of 64 tons to the square mile, or if it had been equally distributed over Victoria, a fall of nearly six million tons in that State Both the minute reddish flakes of sediment and the diatoms and sponge spicules show that the material had been derived from the arid regions in the north west of Victoria and in Central Australia

Climatic Changes in East Africa—In a recent lecture to the Royal Geographical Society, Dr L S B Leakey gave an account of the old lake terraces of the East African rift valley lakes of Nakuru, Elmenteita, and Naivasha All these lakes would appear to date from the mid Pleistocene period Dr Leakey claims to be able to trace the following sequence of events in Lake Nakuru a high level lake left a terrace at 775 feet above the present level, this fell to 250 feet, rose to 510 feet, and, lastly, fell until it dried up completely Afterwards, in a wetter climate, the waters rose again to 375 feet and then fell, and desiccation again occurred Comparable evidence is obtained from Lake Naivasha and elsewhere in East Africa It shows two major pluvial periods, with oscillations, separated by a dry period, during which faulting and volcanic activity were noteworthy The first and second of these pluvial periods Dr Leakey calls respectively the Makalian and Nakuran periods, and these he correlates with the Buhl and sub Atlantic wet phases of Europe

The Gyromagnetic Effect—The University of California has issued, as a pamphlet of 43 pages, Prof S J Barnett's Research Lecture delivered before the University on "Gyromagnetic Phenomena" When a magnet rotates about its magnetic axis, the gyrostatic action of the electrons brings their planes of rotation towards that of rotation of the material of the magnet and the rotations in the same direction This changes the magnetisation of the magnet, and Prof Barnett used two methods of measuring the change The first depended on the change of the magnetic induction through a coil surrounding the magnet and connected

to a magnetic flux meter; the second on the change of the magnetic field produced by the rotating magnet at a magnetometer needle in its vicinity Both methods gave results which agree in showing that the electricity in motion in a magnetic molecule is negative, and that the gyromagnetic ratio is 1 04 m/e for iron and 1 05 m/e for permalloy, while the theory of the planetary atom predicts 2 m/e Prof Barnett concludes that the electron is a negatively charged sphere spinning about its axis without distortion, which would give the ratio m/e, and that such electrons constitute the chief part of the elementary magnet

Raman Effect for Water—An application of the Raman effect to the study of the composition of water and of its variation with temperature and other conditions is described by I R Rao in the February number of the *Proceedings of the Royal Society* Mercury arc excitation was employed, and the rather broad band which appears with a shift corresponding to about 3μ examined with a microphotometer The explanation offered of the temperature changes is that water consists of single, double, and triple molecules, and that the relative number of the single ones increases with temperature Addition of at least the electrolytes which have been studied also appears to increase the proportion of single molecules, but in this case there is the complication of a new hydrate band superposed on the pre existing water band The explanations of the changes which have been proposed by Dr Rao bear a certain resemblance to those which have been offered for the existence of anomalies in the specific heats of solutions of electrolytes, although no comparison of the two sets of phenomena is presented in this paper

New Measurements of Cosmic Radiation—Some very accurate measurements on the absorption of the cosmic radiation, made with an electroscope containing gas at a pressure of 30 atmospheres, are reported by R A Millikan and G H Cameron in the first February number of the *Physical Review* Their older results have been made more exact for all thicknesses of absorbing material and have also been extended both towards harder and softer components The conclusions drawn are much as before It is concluded, on the basis of the Klein Nishina formula, that there is *quantitative* evidence that the strongest and most easily absorbed cosmic ray band arises from the formation of helium out of hydrogen, and it is considered that there is also good *qualitative* evidence that the three more penetrating bands are due to formation from hydrogen of the oxygen, silicon, and iron groups of elements Prof Millikan and Dr Cameron take the view that some of their results require a participation of the nucleus in the absorption process and refer to some work which has been done upon ordinary gamma radiation as supporting this The point raised is naturally a very important one, as it would imply that the Klein Nishina formula is only approximate, and has also been referred to by Dr L H Gray in a paper in the February number of the *Proceedings of the Royal Society* Dr Gray states that he has experiments now in progress which are designed to reveal any evidence for emission of a secondary radiation from such nuclear interaction

Scattering of X-Rays—An important development in the technique for the examination of scattered X-rays is described in the *Physical Review* for Jan 15, by J W M DuMond and H A Kirkpatrick Two of the main difficulties which arise consist in the exact definition of the angle of scattering, and in obtaining a quantity of scattered radiation which can be recorded by photography in a reasonable time These have been, to a large extent, overcome by the adoption of a new form of multi crystal spectrograph Fifty small perfect crystals of calcite are mounted with Seeman wedges on an arc of a circle, and so arranged that they all reflect a standard line—in this case the $K\alpha$ doublet of molybdenum—to exactly the same point on a photographic film coinciding with an opposite arc of the same circle, the geometry of this arrangement is then such that all other wave lengths and orders will be in focus on the same circle The scattering body is set so that each crystal is protected by a pair of baffles from all radiation except that scattered from a small area, and the X ray bulb, scatterer, and spectrograph arranged so that all the crystals receive only radiation scattered through a range of less than one degree about the mean angle of scattering The troublesome background of general scattered radiation is almost entirely eliminated by the baffles, and the radiation which is scattered without change in wave length appears with excellent definition The radiation which has undergone the Compton change in wave length is, however, definitely spread over a range of wave lengths, the breadth of which increases with increase in angle of scattering This lack of sharpness, although not in complete agreement with the results of earlier investigations, appears to be real, and is ascribed to the fact that the electrons responsible for the scattering have an initial motion in addition to the speed imparted to them in the scattering process

Resolution of *dl* Menthol—Although the naturally occurring l menthol is fairly readily obtained by the resolution of dl menthol, the method does not yield d menthol in quantity Read and Grubb, in the January number of the *Journal of the Chemical Society*, show that a mixture of l menthyl-d camphor 10 sulphonate and the corresponding d menthyl compound, easily obtained by the interaction of dl menthol and d camphor 10 sulphonyl chloride in quinoline, yields the first of these esters in a state of purity after four crystallisations The odour of pure d menthol is fainter than that of l menthol The crystallographic data for d menthol, which can be obtained from ethyl acetate solution in very large, magnificent prisms, are given in the paper

Numerical Solution of Differential Equations—In an extensive memoir (*Bulletin* of the Academy of Sciences of the Ukraine 1930 31, in the Ukraine language), E Remes gives a comprehensive survey of previous work on the numerical solution of differential equations, and contributes some valuable new methods The methods of Runge and of Adams (or, as the Russians say, Adams Stormer) are of great practical value, but they have the defect that they do not indicate exact limits between which the error must lie A method for the determination of such limits was given by Piaggio but in a form unsuitable for practical application Remes has now combined the advantages of both methods The memoir has several worked examples, showing the application to single differential equations and also to systems of such equations The work is complicated, but in cases where great accuracy is desirable, the results justify the labour involved As an alternative to Adams's method, little known formulæ, due to Steffensen Stekloff, are given (Mr Remes and his colleagues at Kieff have sent to University College, Nottingham, a quantity of Russian work on the numerical solution of differential equations, including A N Kryloff's valuable book on this subject, together with manuscript translations or summaries in French or German These may be borrowed for a short period by university librarians)

Electrical Industry and Research

SEVERAL notable developments have taken place in the research laboratories of the Metropolitan Vickers Electrical Co, Ltd, during the past year The investigations on the 'creep' or deformation of metals under stress at high temperatures have led to definite results which are of importance in mechanical engineering It has been proved that even at the lower stresses and temperatures of turbine practice steels cannot be regarded as permanently elastic materials They are subject to gradual stretch or other permanent distortion A quick method of testing steels has been developed in the laboratories, and they can now be placed in order of merit after a duration test of only a few days 'Creep' tests as ordinarily applied may last for months A particular sample was subjected to test for twelve months and was found to creep at the rate of one part in a hundred million per hour For the next two months, however, after the year was completed, it only increased at a tenth of this rate The limit of sensitivity of the apparatus has now been reached, but it is not yet possible to say definitely that creep has ceased If we consider a turbine cylinder 100 inches in diameter and subject to a rate of increase of one part in a hundred million per hour over a period of ten years, its diameter would have increased by nearly one tenth of an inch, and this increase would seriously limit the life of the turbine Other useful mechanical researches are being made in the laboratory as to the effect of surface hardening on the fatigue resistance of gear wheel teeth The results obtained are of great use in designing the best driving gears for electric trams and locomotives

Noise problems are being specially studied in the acoustics laboratory of the Metropolitan Vickers Electrical Co, Ltd The results of this work have been applied in the design of several new sizes of silent type direct current motors These motors have proved specially useful for ship ventilation Good progress has also been made in building alternating current motors that will run quietly

In the high voltage laboratory a comprehensive research has been made on various kinds of dielectric material when subjected to different kinds of stresses, namely ordinary alternating voltages up to a million volts at low frequencies, impulsive voltages, high frequency voltages and steady unidirectional voltages By means of a new cathode ray oscillograph, impulse rushes having definite characteristics can now be applied to the materials The results obtained in this way will be of use in protecting transmission lines and connected apparatus against abnormal voltage rushes These are produced by the steep fronted surges which sometimes arise in the lines and are due either to switching operations or to lightning discharges in the neighbourhood of the line These rushes of electricity are specially serious when they cause resonance effects in the circuit owing to capacitance and inductance An ordinary oscillograph would be useless for studying these phenomena, which last only a few millionths of a second The new cathode ray apparatus developed in the laboratory during two years' research is now in everyday use in conjunction with the million volt lightning generator The rapidity of the response of the oscillograph depends on the great speed of the electron beam, the complete response only taking the two hundred millionth part of a second A reasonable deflection can be obtained with only a few hundred volts

Equally interesting developments in the work of the General Electric Company are recorded in the February issue of the *G E C Journal* Progress in research and technical development is largely independent of trade cycles In a progressive country, the fact that business conditions may be difficult acts more as a stimulant than as a deterrent to scientific advancement Although there has been no epoch making discovery during the last year, yet the total progress made by the G E C compares very favourably even with years containing spectacular achievements

Advances have been made in electric discharge tubes for lighting purposes Neon tubes need no replenishing, as this gas does not disappear appreciably even after running for thousands of hours When pure it gives an orange red colour, but the introduction of a small quantity of mercury makes it a brilliant blue By tinting the glasses and using various mixtures, several new colours have now been introduced A few months ago the 'ripple' type of discharge was discovered The luminous glow in ripple lamps only fills a fraction of the diameter and forms a luminous cord which, instead of remaining stationary along the axis of the lamp, wavers about with a strange but attractive sinuous motion The discharge tubes require high voltages but take very little current A low voltage tube has been invented which operates on low voltages but takes a large current

Improvements have been made in the manufacture of the loading coils used for long telephone cables The cores of these coils are made of a new alloy called 'gecalloy' The manufacture of this alloy involves new methods of making a nickel iron alloy powder Special precautions are necessary to insulate the particles so as to prevent eddy currents By insulating and compressing the iron dust, cores with a permeability lying between 20 and 35 have been obtained One great advantage of these new coils is their small size, as hundreds of coils may need to be installed in a small manhole

A productive research has been made by the G E C Research Laboratories on photo cells as there is a considerable demand for them by the sound film industries A valuable device has been perfected, and is now produced in bulk, for the protection of railway substations from voltage rises It depends for its action on the operation of a neon valve of high current capacity which becomes a conductor at 160 volts It is capable of carrying 3000 amperes for three minutes without undue heating

It is interesting to read that two Diesel electric locomotives were shipped for the Indian State Railways during the past year, and that much development work has been done in connexion with omnibuses operated from overhead trolley wires The most important work was done in connexion with the Manchester Altrincham line electrification This is the first suburban electric railway in Great Britain to be operated at 1500 volts on the direct current system The trial runs have been entirely satisfactory. The electric heating of the coaches from a 1500 volt supply proved to be a difficult problem, as the operation had to be 'mistake proof'

The requirements of the artificial silk industry have led to the production of a motor for driving spinning bowls at 10,000 revolutions per minute This gives a peripheral speed of 3½ miles per minute Enormous lamps, some of them taking 10,000 watts, have been sold to British and Continental cinema studios Very satisfactory progress has been made in the manufacture of oil filled underground cables Three core cables, oil filled, can now be made for 66 kilovolt working

In the article on the mass production of incandescent electric lamps at the G E C factory at North

Wembley, a spirited defence is made of mass production The chief complaint about this method is that the products lack individuality, and hence the inference is sometimes erroneously drawn that they are 'inferior' From the economic and from nearly every other point of view, mass production is the best Unfortunately, there seems little prospect of voltage standardisation—even in Great Britain seven voltages lying between 200 and 260 are in use—and there seems no hope of world agreement Although great efforts have been made to standardise the diffusing 'pearl' finish for the bulbs, many users cling obstinately to the time honoured glare of the unshaded bulb The factory produces no less than 84 different types of product This large number is made necessary by the lack of standardisation in the country

Biological Oxidation

ON Mar 6, Prof H Wieland gave the second Pedler Lecture before the Chemical Society his subject being "Recent Researches on Biological Oxidation" Attempts have been made, he said, to formulate the vital process of combustion according to a single scheme A 'respiratory ferment' catalysing the process is considered by Warburg to be related to hæmin, and Liebig put forward the hypothesis that iron accelerates vital oxidations If we adopt this view, we are faced with the difficulty of understanding why the activated oxygen does not indiscriminately oxidise every substance which the cell presents to it Yet if the process of biological hydrolysis is not carried out by any single ferment system, each kind of substrate being split by its own specific enzyme, it is unlikely that a single catalyst will suffice for the much more complicated process of the oxidative destruction of organic molecules

No fundamental difference is encountered in the nature of enzymes throughout the vast range of living organisms, ascending from unicellular fungi to man, yet we lack the means with which to accomplish the complete degradation, by dead material of a substrate familiar to the cell Hence it would appear that the available enzymatic activity of respiration is closely connected with that regulating principle which, for want of more exact knowledge, we can but describe by a circumlocution called life Since the higher we go up the phylogenetic scale the more delicate and complex becomes the nature of biological oxidation, a preliminary study should be concerned with the aerobic fungi

Prof Wieland discussed the mechanism of the acetic acid fermentation characterising the transformation as a dehydrogenation process, since quinone or methylene blue may replace the oxygen The aerobic process is inhibited by quinone as well as by hydrocyanic acid, the difference being that only the former participates in the enzymic reaction The intermediate formation of hydrogen peroxide as a primary product of biological oxidation is not easy of demonstration, on account of the presence of catalases which cannot, as a rule, be separated from the dehydrases and are also sensitive to hydrocyanic acid The study of milk, however, affords such an opportunity Prof Wieland said that the observation of reducing action in the cell does not necessitate postulation of the existence of special reducing ferments, for reduction products would be formed by the intervention of various hydrogen acceptors in the process of dehydrogenation The enzyme reactions of milk have also contributed to an understanding of catalase action, which appears to be biologically related to the utilisation of oxygen by the cell The two dehydrogenating ferments of milk are clearly of general biological importance, since they have been found also in the liver and other organs

A third enzyme system, found in muscle, is concerned chiefly with the dehydrogenation of succinic to fumaric acid, and both oxygen and methylene blue act as acceptors of the hydrogen This reaction can be followed further biologically to the pyruvic acid stage, and probably even beyond this Pyruvic acid, as a product of the dehydrogenation of lactic acid, is on the main line of biological degradation If we accept enzymic reactions involving hydrogen peroxide, with hydrolysis and condensation, as conditions governing cellular metabolism we facilitate an understanding of the energy changes which constitute the life of the cell

Discussing the correlative oxidation and reduction of aldehydes, Prof Wieland referred to the aldehydrase, which was first described as a reducing enzyme in milk, was later also recognised as an oxidase and is moreover able to dismute aldehydes into acid and alcohol Although the theory that a heavy metal— more particularly iron—takes part in biological oxidations has acquired a certain measure of probability, the recognition of iron as a constituent of oxidising enzymes in no way implies that it functions as an oxygen activator Ferrous iron rather associates itself with the substrate of the oxidation, forming a complex in which the hydrogen atoms to be removed in the dehydrogenation process become labile A clear understanding of the complex course of biological oxidation has, however, not yet been obtained We must advance step by step by the study of such chemically intelligible partial reactions as can be followed accurately

Plantation Rubber Research

THE Annual Report of the Rubber Research Institute of Malaya for 1929 covers the third completed year of active operation, as although the Institute came into existence on Sept 1, 1925, its activities can only be said to date from the appointment of a director in September 1926 The revenue of the Institute is nominally provided by the Governments of the Straits Settlements, Federated Malay States, Johore, Kedah, Kelantan, and Trengganau from a cess on exported rubber, but with the exception of the last, the cess has not been levied, equivalent payments out of revenue having been made Since July 27, 1929, Major B J Eaton has acted as director, an appointment which has recently been confirmed and changes in personnel and shortage of staff hindered the work of the Institute in several directions during the year, notably in the advisory work on behalf of estates A considerable proportion of this advisory work on problems such as manuring, budding, and seed selection, replanting and rejuvenation of rubber areas, is essentially applied research, and useful and valuable results are anticipated Such practical work may indeed require to precede the slower process of scientific development, and the film propaganda among small holders, for which a motor van and apparatus have been approved, should materially help in the development of better conditions on small-holdings

An important division of the Institute is concerned

with soil investigations Our knowledge of and methods of soil investigation are, however, not sufficiently advanced, particularly in connexion with permanent crops such as rubber, to enable recommendations to be made in many cases from the results of a soil analysis alone Short and rapid methods of analysis are being investigated, and valuable information is being obtained as to probable soil deficiencies, particularly in nitrogen and potash, from field observations The problem is specially important in relation to the manuring or rejuvenation of very poor areas of rubber Other work in the same division is concerned with soil conservation and bacteriology, and studies of the relation of soil fungi and bacteria to the soil humus and of the value of leguminous and green cover crops to soil bacteria have been commenced

The botanical division has reported considerable progress in such practical problems as budding, and investigations on the artificial pollination of flowers (from various classes on Pilmoor estate) and on seed selection have continued No new diseases of importance are reported, but the pathological division directs attention to the urgent need for a thorough investigation of the relative value of well known fungicidal chemicals compared with proprietary fungicides Many of the latter are equally effective, and their use is determined chiefly by relative cost A determination not only of the fungicidal properties but also of their penetrative effect on the parts of the plant treated is required Differences in penetrative power affect the toxicity, and this is specially important in regard to bark renewal on the tapping panel The problem of 'mouldy rot' caused by the fungus *Sphaeronema fimbriatum* is one of special interest in regard to fungicidal treatment, which is also important in the case of secondary leaf fall due to the mildew fungus *Oidium Heveæ*, owing to the danger of the fungus becoming more adapted to the host

Investigations at the Institute have thrown new light on the origin and incidence of 'brown bast' Chemical and bacteriological investigations of the production of white sole crepe—the demand for which is regarded as retrograde—the preservation of latex, effects of moulds on rubber and on various factory problems are reported, while considerable progress has been made on the experimental station 905 acres out of the approximately 2000 acres having now been opened 571½ acres of this have been planted and preliminary records of value should be available during 1930 The value of treating young rubber with cattle manure on a particular type of soil has already been demonstrated

University and Educational Intelligence

Cambridge —The Appointments Committee of the Faculty of Physics and Chemistry has appointed Mr P M S Blackett King's College, to be University lecturer in physics, Dr P J Durrant, of Selwyn College, and Dr F P Bowden, of Gonville and Caius College to be University demonstrators in chemistry

The General Board has recommended that a readership and a University demonstratorship in geophysics be established in the Faculty of Mathematics, and that Dr H Jeffreys, of St John's College, be appointed reader

Dr J Wishart has been appointed University lecturer in statistics in succession to Mr G Udny Yule, who has been appointed reader in statistics

The Sedgwick Prize for 1931, for an essay on geology, has been awarded to Dr C E Tilley, of Emmanuel College

London —The following doctorates have been awarded *D Sc in Chemistry* to Mr A M Ward, Birkbeck College for a thesis entitled "Investigations on the Bivalency of Carbon", consisting of four published papers (*Jour Chem Soc*, 1927, 1929, 1930), *D Sc in Physics* to Mr S H Piper, King's College, for a thesis entitled "X ray Studies of Long chain Compounds", comprising three published papers (*Jour Chem Soc*, 1929, *Trans Far Soc*, 1929, and *Proc Roy Soc*, A, 1930), *D.Sc in Entomology* to Mr W J Hall, Imperial College—Royal College of Science, for a thesis entitled "The South African Citrus Thrips in Southern Rhodesia" and "Observations on the Coccidæ of Southern Rhodesia", parts 1 3, and eight subsidiary contributions, *D Sc in Geology* to Dr A Brammall for a thesis entitled "Gold and Silver in the Dartmoor Granite" (*Min Mag*, vol 21, 1926), "The Dartmoor Granite" (*Proc Geol Assoc*, vol 27, 1926), "Dartmoor Detritals—A Study in Provenance" (*Proc Geol Assoc*, vol 39, 1928), "Notes on Fissure Phenomena and Lode-Trend on Dartmoor" (*Trans Roy Geol Soc of Cornwall*, vol 16, 1928), and eight subsidiary contributions

During the seventh year of the Ella Sachs Plotz Foundation for the advancement of scientific investigation, seventy eight applications for grants were received by the trustees, sixty two of which came from twelve different countries in Europe and Asia, the remaining sixteen coming from the United States The total number of grants made during this year was twenty five, one of these being a continued annual grant Twenty one of the new grants were made to scientific workers in countries outside the United States In the seven years of its existence, the Foundation has made one hundred and twenty grants and investigators have been aided in the United States, Great Britain, France, Germany, Austria, Hungary, Switzerland, Italy Sweden, Esthonia, Czechoslovakia, Poland, Chile, Syria, and Belgium Applications for grants to be held during the year 1931–32, to be sent to Dr Joseph C Aub, Collis P Huntington Memorial Hospital 695 Huntington Avenue, Boston, Massachusetts, should be in the hands of the Executive Committee before May 1, 1931

The Carnegie Trust for the Universities of Scotland has allocated, as grants for the quinquennium ending September 1935 for universities and extra mural institutions respectively, £224,700 and £34 325 Since the Trust's operations began in 1902, the total grants have been distributed as follows for libraries, £159,850, buildings and permanent equipment, £905,101, endowment of chairs, lectureships, and pension schemes, etc, £437,701, other purposes, £143 730 A noticeable feature of the last quinquennial allocation is the assistance towards such student purposes as residential halls, students' unions, and playing fields, which have always specially appealed to the Trust Assistance to students in payment of class fees for 1929-30, accounting for nearly half of the Trust's expenditure, amounted to £56,316, distributed among 4531 beneficiaries Voluntary repayments by 54 former beneficiaries (21 men and 33 women) amounted during the same year to £2036 Apart from the quinquennial grants scheme and assistance to students, the Trust spent last year on fellowships, scholarships, and other grants for the endowment of research, £19,516 Under its research scheme the Trust recently instituted senior scholarships, of the annual value of £200, to provide, in particular, for the Ph D candidate, who must generally be engaged for three years at post graduate work before he presents his thesis for that degree

Birthdays and Research Centres.

Mar 15.—Prof C V BOYS, F R S, past president of the Physical Society of London

In NATURE of July 13, 1929, p 54, I gave a diagram of a more powerful camera for observing the progressive movement of lightning Since then I have had one of these cameras made by Messrs Ross, Ltd I have not been able to try this on real lightning, but last spring Mr Goodlet, late of the Metropolitan Vickers Electrical Co, Ltd, allowed me to photograph their high tension sparks I never expected that I should be able to observe any 'progress' in this artificial lightning five feet long only, but running the film at approximately 100 miles an hour I obtained sharp rather over exposed images With Tesla sparks the photographs show perfectly sharp but very pale images of extraordinary tenuity The real object of the experiment was to prove the satisfactory running of the instrument and its optical perfection In these respects it could not be improved upon I sent this to Mr Loomis, and he and Prof R W Wood have had it for the greater part of one summer, but they have so far not succeeded in catching anything However, I succeeded in obtaining a photograph during the great storm on Aug 29 last with my original camera, but only when the lightning was too close Moreover, the two flashes caught were very much to one side and the nearer one had the greater part of one image off the plate altogether The other pair of images gives some stereoscopic indication of progress, but it must be remembered that the longer the image on the plate the less conspicuous will this be For this reason it is desirable that lightning should not be nearer than five or six miles The short focus lenses in the new camera and the higher speed attainable make this instrument ten or more times as powerful as the original camera which I made in 1900 As I had to wait twenty eight years before obtaining my first picture, which was taken in America (see NATURE, Nov 20, 1926, p 749), and got only a useless one last year, it would seem desirable that more than one of the new cameras should be available in suitable observatories, for information as to the progress of a lightning flash can be obtained in no other way, and any information so obtained is unassailable

Mar 17, 1876.—Dr F J W WHIPPLE, superintendent of Kew Observatory

The principal subject of investigation at Kew Observatory at present is the circulation of atmospheric electricity In fine weather, there is a continuous, though small, current of positive electricity from the air to the ground, in disturbed weather, currents in the reverse direction are the more frequent There is much to learn about these currents and their relation to other atmospheric conditions, such as potential gradient, dust content, ionisation, conductivity, and radioactivity

My own attention has recently been given to questions raised by the observations of the propagation of air waves to great distances, and especially by the numerous observations which have been made during the last four years of the air-waves from gunfire It is hoped to obtain from such observations reliable information as to the variations in the temperature of the atmosphere at heights of 40 km and upwards, where the absorption of ultra-violet light by ozone heats up the air

Mar 19, 1871.—Prof WILLIAM ARTHUR BONE, F R S, professor of chemical technology in the Imperial College of Science and Technology

At present I am working on (1) The chemical constitution of coals, as a problem in organic chemistry, with the object of ascertaining the essential molecular structure of the coal substance, its relation to the lignins, etc, from which it originated, the chemical aspects of its maturing, and the development of the coking propensities of bituminous coal (2) Gaseous combustion and explosions, more particularly (a) the slow combustion of hydrocarbons, (b) the function of steam in the combustion of carbonic oxide, (c) the photographic analysis of 'detonation' in gaseous explosions, and (d) gaseous explosions at very high initial pressures, for example, between 500 and 1000 atoms (3) Catalytic gas reactions at high pressures (4) The chemical reactions involved in the blast furnace smelting of iron ores, with the view of providing a fundamental basis for fuel economy and control in this operation

I believe that the proper function of university departments of applied science is to carry out systematic researches of a fundamental character into general problems underlying industrial practice, rather than investigations of particular works' problems, which can best be tackled by industrial research organisations

Societies and Academies

LONDON

Royal Society, March 5.—**W L Garstang** and **C N Hinshelwood** The kinetics of the combination of hydrogen and oxygen the influence of iodine *The surface reaction in vessels of silica and porcelain* is accelerated by iodine The amounts of iodine required are small The efficiency of collisions with iodine in breaking chains is, however, less than about 10^{-4} Water vapour lowers the upper critical limit of the low pressure explosion region and in sufficient amount, inhibits the explosion altogether Commercial hydrogen appears to contain no inhibiting substances —**D R Hartree** Optical and equivalent paths in a stratified medium, treated from a wave standpoint Wave treatment is essential for the interpretation of some of the phenomena of reflection from the Heaviside layer Expressions for the optical and equivalent paths in terms of the solutions of the equations of wave propagation are obtained, both for normal and oblique incidence, and exact expressions are obtained for the optical path for normal incidence on stratified media with certain simple variations of refractive index Approximate expressions are obtained for the optical and equivalent paths in a totally reflecting medium —**H J Phelps** The adsorption of substances by fuller's earth The adsorption of weak solutions of various organic acids and bases has been studied, in particular, attention is directed to a study of the adsorption of such substances from solutions of various hydrogen-ion concentrations The adsorption of the simple amines is molecular, or 'apolar', in solutions of reaction more alkaline than pH 9, while it is ionic, or 'polar', in solutions more acid than about pH 8 The adsorption of bases and also of oxalic acid falls to zero in solutions more acid than pH 3, due to the fact that the calcium salts in fuller's earth, the presence of which is essential for adsorption to take place, are soluble under these conditions —**L J Mordell** The arithmetically reduced indefinite quadratic form in n variables A simple method is given for finding inequalities satisfied by the coefficients of a reduced indefinite form When the coefficients are integers a simple proof is given that the class number for forms with given determinant is finite A normal type is also found for the reduced forms —**A E Moelwyn Hughes** and **C N Hinshelwood** The kinetics of reactions in solution (1, 2) The decom-

position of chlorine monoxide in carbon tetrachloride solution proceeds at the same rate, possesses the same heat of activation, and apparently takes place by the same mechanism as in the gaseous state The retardation of bimolecular reactions by solvents thus appears to depend upon a specific influence of particular solvents, and need not occur in an 'ideal' solution The aim of the experiments was to determine whether constancy of rate and heat of activation with change of solvent can be regarded as the usual characteristic of a unimolecular reaction It is concluded that it is only true of certain 'ideal' solvents —**F R Terroux** The upper limit of energy in the spectrum of radium *E* The velocities of the fastest β rays from radium *E* were determined from the curvature of the tracks in a magnetic field and the distribution of the rays obtained in the region extending from 4000 to 10 000 $H\rho$ The complete spectrum of radium *E* was obtained by combining the present observations with previous work and the resulting curve shows no trace of the hitherto accepted end point at about 5000 $H\rho$ The spectrum appears to tail off very gradually and to extend at least to 12,000 $H\rho$, which corresponds to an energy of 3,000 000 electron volts The number of particles above 5000 $H\rho$ is about 4 per cent of the total number emitted An energy distribution curve was obtained, and from this the average energy per disintegration is estimated at about 473,000 volts, with a probable error of 20 per cent which is in fair agreement with the values obtained from heating measurements It appears probable that the β particles from radium *E* are emitted from the nuclei according to a simple distribution law which resembles the Maxwellian form and that there is a finite probability for the emission of a particle with any velocity —**K R Rao** and **J S Badami** Investigations on the spectrum of selenium—(1) The spectrum of selenium has been investigated from λ7000 to λ650, mainly using different intensities of discharge through capillary tubes containing vapour of selenium Between λ1400 and λ400 vacuum spark spectra have been taken with and without inductance With the aid of these data the doublet system of trebly ionised selenium has been identified A few singlets and inter combination lines in Se V have been added to the triplet system that was already known The largest term, $4s\ ^1S_0$ is found to be 589,781 cm^{-1}, leading to an approximate ionisation potential of 72 8 volts —**J K L Macdonald** Stark effect in molecular hydrogen in the range 4100 4770 A Certain complex structures reported by Kiuti are resolved into independent lines Displacements of line components are measured and the observations are considered from a theoretical point of view Certain groups of *P* and *R* branch lines with common initial levels are found to be adequately described, as regards number and polarisation of components, by a theory which is briefly discussed —**T Alty** The reflection of vapour molecules at a liquid surface The rate of evaporation from a water surface is measured as a function of the vapour pressure above the evaporating surface By extrapolation to zero pressure the rate of evaporation into a vacuum is found On comparing this experimental result with the formula of the kinetic theory of gases for the number of vapour molecules striking a water surface per second from the saturated vapour, it appears that only about 1 per cent of the molecules incident on the surface are able to enter the liquid

PARIS

Academy of Sciences, Jan 19 —**H Douvillé** The eruptive rocks of the Pic de Rébenacq —**André Blondel** The improvement of the present system of electromagnetic units If the units of E M F and current are taken as 10 volts and 10 amperes and the power unit as the hectowatt, leaving the ohm and the farad unchanged, then such a system contains only 10^9 and 10^{-9} in all its elements In the C G S system the new prefixes 'nea' for 10^9 and 'cato' for 10^{-9} are suggested The deficiencies of the present system of nomenclature are fully discussed —**C de la Vallée Poussin** The conformal representation of multiply connexe plane areas —**W Vernadsky** Isotopes and living organisms A discussion of the possibility of living organisms possessing the property of separating isotopes, in the course of their life —Richard Fosse was elected a member of the Section of Rural Economy in succession to the late A Th Schloesing, and Eugene Fabry *correspondant* for the Section of Geometry in succession to the late M Riquier —**A Norden** The inclusion of the metric and affine theories of surfaces in the geometry of specific systems —**Rachevsky** Congruences with several dimensions —**G Gourewitch** The divisibility of trivectors and quadrivectors by a vector **Mlle Marie Charpentier** A certain class of Peano points —**Basile Demtchenko** A mixed problem in the ring —**Raphael Salem** The necessary and sufficient conditions that arbitrary constants a_n, b_n should be Fourier coefficients of a function capable of summation —**Emile Belot** The origin and formation of Pluto according to the dualist cosmogony —**Gr C Moisil** Wave mechanics of fields of waves —**L Brüninghaus** The electrical conduction of liquid hydrocarbons in thin layers A drop of fresh vaseline oil, inserted between two electrodes 11 μ apart, closes a 110 volt continuous circuit "as if it were a drop of mercury" This conducting state is abolished when the electrodes are 15 μ apart —**J M Cork** Change of wave length of the X rays traversing an absorbing medium (observed in the direction of transmission) An attempt to repeat some experiments recently described by B B Ray (NATURE, 125, p 856) has given only negative results possibly due to the different screens employed —**J Dourgnon** and **P Waguet** Remarks on certain photometric properties of ground and grained glass —**J P Mathieu** A method of measuring circular dichroism **Jean Loiseleur** and **Léon Velluz** The association of biochemical constituents and certain cellulose esters Details of technique for preparing membranes containing cellulose acetate and casein or other proteins —**A Travers** and **J Aubert** The potential of passive iron From the results of the experiments described, it is concluded that the term 'passive iron' has no absolute meaning, there are degrees of passivity The film of oxide theory of passivation cannot apply in all cases, since the potential of iron immersed in different oxidising agents depends on the nature of the latter —**André Michel** and **Pierre Benazet** The reheating of rapidly tempered steels —**P Brauman** The alkyl oxyvanadylsalicylates of alkyls and aryls —**Raymond Furon** The geology of the Gabon (French Equatorial Africa) —**R Bureau** A recording radiogoniometer Its application to atmospherics Ranzi's neon lamp method has been modified to record not only the variations of the atmospherics but also their direction Two diagrams are reproduced —**Louis Dangeard** The lower algæ in the Limagne limestone —**Jules Amar** Hydrodiffusion and deadly fogs —**Pierre Lavialle** The stamen in *Knautia arvensis* The polymorphism of the flowers and flower heads —**Emile Saillard** The precipitation of lime by sulphurous acid in sugar solutions —**Ph Joyet-Lavergne** The conditions of metabolism permitting the realisation of the change of sex —**Georges Blanc** and **Jean Valtis** The sensibility of *Spermophilus citillus* to experimental tuberculous infection —**F Dienert** and **P Etrillard** The sterilisation of water by metals

Diary of Societies

FRIDAY, MARCH 13

INSTITUTION OF MUNICIPAL AND COUNTY ENGINEERS (Scottish District Meeting) (at City Chambers Edinburgh), at 11 30 A M —W B Scott The Proposed National Standard Practice for the Employment of Structural Steel in *Building*, as Delegated by the *British Steel Work* Association

BIOCHEMICAL SOCIETY (Annual General Meeting) (at University College), at 3.—Prof C Lovatt Evans, Chiao Tsai, and F G Young A Note on the Estimation of Liver Glycogen —R A McCance and H L Shipp The Colorimetric Determination of Sodium —E Stedman and Ellen Stedman Studies on the Relationship between Chemical Constitution and Physiological Action Part III The Inhibitory Action of Certain Synthetic Urethanes on the Activity of Liver Esterase — B C J Knight An Electrolytic Method for Poising the Oxidation reduction Potential of Culture Media.—G F Marrian Observations on the Physiological Potency of Crystalline Tri hydroxy Œstrin — Prof T P Hilditch and J J Sleightholme The Glyceride Structure of Butter Fats.—H R Ing and R N Kekwick A Note on Acyl Derivatives of Creatine and Creatinine.—I S MacLean and M S B Pearce Oxidations of Oleic Acid *in vitro* and their Bearing on the Biological Oxidation of Oleic Acid —C Rimington and A M Stewart A Pigment from the Suint (Sweat Fraction) of Raw Sheep s Wool

ROYAL SOCIETY OF ARTS (Indian Meeting), at 4 30 —Dr H H Mann The Tea Industry of India in its Scientific Aspects

ROYAL ASTRONOMICAL SOCIETY at 5 —Sir A S. Eddington A Theorem concerning Incomplete Polytropes J Young Occultations of Stars by the Moon observed at Birmingham University during 1930 —T Matukuma Relativity Effect in the Problem of Latitude Variation —J Dufay Effect of Atmospheric Absorption in Stellar Spectrophotometry J H Hindle A New Test for Cassegrain and Gregorian Secondary Mirrors —V V Narliker The Significance of Bode s Law in Relation to Satellite Systems —L H Thomas The Slow Contraction and Expansion of a Fluid Sphere II Stability —S Chandrasekhar The Dissociation Formula According to the Relativistic Statistics —C S Beals Wave Lengths of Oxygen and Nitrogen Lines in the Stellar Region Royal Observatory Greenwich Observations of Solar Flocculi made with the Spectrohelioscope during 1930 — Dr H H Plaskett The Formation of the Magnesium *b* Lines in the Solar Atmosphere —B Strömgren The Possible Solutions of the Equations of Fit on the Standard Model T G Cowling Note on the Fitting of Polytrope Models in the Theory of Stellar Structure — S Chandrasekhar The Highly Collapsed Configurations of a Stellar Mass

ROYAL SOCIETY OF MEDICINE (Ophthalmology Section) (at Middlesex Hospital) at 5 —Clinical Meeting

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5 —Sir Arthur Keith Demonstration of Specimens illustrating the Anatomy Physiology, and Pathology of the Œsophagus

ROYAL SOCIETY OF MEDICINE (Clinical Section), at 5 30

MALACOLOGICAL SOCIETY OF LONDON (at Linnean Society) at 6 —H H Bloomer On the Anatomy of *Bruguiera* cf *aneyi*, Bourguignat — J R le B Tomlin Two New Species of *Ishiostoma* —C Oldham Some Scalariform Examples of *Helicella arbustorum*

NORTH EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (at Mining Institute Newcastle upon Tyne) at 6 —S F Dorey Some Factors Influencing the Sizes of Crankshafts for Double Acting Diesel Engines

INSTITUTION OF ELECTRICAL ENGINEERS (London Students Section) at 6 15 —C J F Tweed Aspects of the Transmission and Reception of Still Pictures

INSTITUTE OF FUEL (North Western Section) (at Engineers Club Manchester) at 7 —Dr G E K Blythe The Industrial Application of Pulverised Fuel

INSTITUTION OF LOCOMOTIVE ENGINEERS (Manchester Centre) (at Literary and Philosophical Society Manchester) at 7 —Dr E G Ritchie Steam Storage in Relation to the Locomotive

OIL AND COLOUR CHEMISTS ASSOCIATION (Manchester Section) (at Milton Hall Manchester) at 7 —Dr F A Mason Recent Lines of Advance in Lake and Pigment Chemistry

JUNIOR INSTITUTION OF ENGINEERS at 7 30 —L Clegg Phenol Formaldehyde Moulding Compositions Manufacture and Use

SOCIETY OF CHEMICAL INDUSTRY (Chemical Engineering Group) (at Chemical Society) at 8 —W J Rees The Manufacture of Lime

ROYAL INSTITUTION OF GREAT BRITAIN at 9 —J C Squire Parody

SATURDAY, MARCH 14

INTERNATIONAL SOCIETY OF LEATHER TRADES CHEMISTS (British Section) (at University Leeds) at 10 A M —R F Innes Determination of Water in Vegetable Tanned Leather —Dr A C Russ New and Improved Method of Moisture Determination and its Application to Leather —Dr D Burton Note on the Determination of Moisture in Leather —H G Bennett and others Discussion on Mineral Acids in Vegetable Leather —Demonstration of a New Form of Tintometer, by Dr J G Parker

ROYAL INSTITUTION OF GREAT BRITAIN, at 3 —Lord Rutherford Recent Researches on the Alpha Rays (2)

BRITISH PSYCHOLOGICAL SOCIETY (at Royal Anthropological Institute) at 3 30 —R. Sedgwick A Brief Restatement of the Case for Psychological Hedonism and an Examination of some Fundamental Concepts in Affective Psychology

MONDAY MARCH 16

VICTORIA INSTITUTE (at Central Buildings, Westminster) at 4 30 —Col F C Molesworth History of Practical Astronomy

ROYAL GEOGRAPHICAL SOCIETY at 5 —W V Lewis The Effect of Wave Incidence on the Configuration of a Coast

ROYAL COLLEGE OF SURGEONS OF ENGLAND at 5 —C E Shattock Demonstration of Specimens illustrating Affections of the Kidney

INSTITUTION OF MECHANICAL ENGINEERS (Graduates Section), at 6 45 — C Day Heavy Oil and Diesel Engines (Lecture)

SOCIETY OF CHEMICAL INDUSTRY (Edinburgh and East of Scotland Section) (Annual General Meeting) (at 36 York Place Edinburgh) at 7 —Dr H Hepworth Invention in Chemical Industry

INSTITUTION OF ELECTRICAL ENGINEERS (Informal Meeting), at 7 —Dr A Rosen and others Discussion on Some Difficulties in A C Bridge *Measurements*

INSTITUTION OF ELECTRICAL ENGINEERS (Mersey and North Wales (Liverpool) Centre) (at Liverpool University), at 7

INSTITUTION OF ELECTRICAL ENGINEERS (Tees Side Sub Centre) (at Cleveland Technical Institute Middlesbrough), at 7 —B Leggett The Medical and Surgical Applications of Electricity

SHIPLEY TEXTILE SOCIETY (at Technical School Shipley) at 7 30 —Prof Barker South Africa its Sheep and Wool (Lecture)

ROYAL INSTITUTE OF BRITISH ARCHITECTS, at 8 —C R. Peers The Treatment of Old Buildings.

ROYAL SOCIETY OF ARTS, at 8.—Capt. A. G. D. West: The Recording and Reproducing of Sound (Cantor Lectures) (2).
EUGENICS SOCIETY (at 20 Grosvenor Gardens, S.W.1), at 8.15.—Study Circle.

TUESDAY, MARCH 17.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, at 5.—Dr. M. Critchley: The Neurology of Old Age (Goulstonian Lectures) (3).
ROYAL INSTITUTION OF GREAT BRITAIN, at 5.15.—Dr. C. D. Darlington: The Cytological Theory of Heredity and Variation (2).
ROYAL SOCIETY OF MEDICINE, at 5.30.—General Meeting.
MINERALOGICAL SOCIETY, at 5.30.—A. J. P. Martin: On a New Method of Detecting Pyro-electricity.—Dr. D. R. Grantham and F. Oates: On the Mbosi Meteoric Iron, Tanganyika Territory.—Dr. S. R. Nockolds: On the Dhoon (Isle of Man) Granite: a Study of Contamination.—A. G. MacGregor: On Clouded Felspars as a Result of Thermal Metamorphism.—C. N. Fenner: On the Residual Liquids of Crystallising Magmas.
ZOOLOGICAL SOCIETY OF LONDON, at 5.30.—Dr. R. Broom: On the *Pygocephalus*-like Crustacean of the South African Dwyka.—Dr. P. R. Lowe: On the Anatomy of *Pseudocalyptomena* and the Occurrence of Broadbills (Eurylaimidæ) in Africa.—J. St. Leger: A Key to the Families and Genera of African Rodentia.—B. W. Tucker: (*a*) Note on a Skull of *Sus gargantua* Miller, in the Cambridge Museum; (*b*) On the Occurrence of *Rana græca* at Small Altitudes in the Naples District, with some Observations on Habits.
INSTITUTE OF METALS (Birmingham Section) (in Chamber of Commerce, Birmingham), at 7.—Dr. C. J. Smithells: The Metallurgy of Some of the Rarer Metals.
ROYAL SOCIETY OF MEDICINE (Pathological Section) (Annual General Meeting), at 8.

WEDNESDAY, MARCH 18.

GEOLOGICAL SOCIETY OF LONDON, at 5.30.—W. B. R. King: A Fossiliferous Limestone Associated with Ingletonian Beds at Horton-in-Ribblesdale, Yorkshire.—Prof. O. H. Schindewolf: On the Septal Development and the Genotype of the Coral Genus *Zetraia* Münster.
ROYAL MICROSCOPICAL SOCIETY (at B.M.A. House, Tavistock Square), at 5.30.—Dr. W. E. Cooke and C. F. Hill: Microscopical Studies in Pernicious Anæmia. (3) The Macropolycyte. (4) Nuclear Degeneration in Blood Stream Cells.—F. G. Wood: Micro-polarising Crystals and their Projection.
NEWCOMEN SOCIETY (at Caxton Hall), at 5.30.—J. G. H. Warren: John Nuttall's Sketch Book and Notes on Wrought Iron Detail for Early Locomotives.
OVERHEAD LINES ASSOCIATION (at Institution of Electrical Engineers), at 5.30.—W. C. Baxon and others: Discussion on Overhead Line Difficulties.
LIVERPOOL ENGINEERING SOCIETY (at 9 The Temple, Liverpool), at 6.30.—G. S. Baker: Horse-power of Ships as Affected by Rudders and Propellers.—R. F. Leggat: Notes on Water-Power Development in Canada.
INSTITUTION OF ELECTRICAL ENGINEERS (Sheffield Sub-Centre) (at Royal Victoria Hotel, Sheffield), at 7.30.—W. Redmayne: Cable Fault Localisation by Telephone Methods.
LEICESTER LITERARY AND PHILOSOPHICAL SOCIETY (Botany and Biology Section) (jointly with Leicester Branch of British Empire Naturalists' Association) (at Leicester Museum), at 7.30.—Mr. Bastard: Why is there no Darwinian Morality?
ROYAL METEOROLOGICAL SOCIETY, at 7.30.—Commander E. C. Shankland: Navigation from Viking Period to Present Day in Relation to Science and Meteorology (G. J. Symons Memorial Lecture).
FOLK-LORE SOCIETY (at University College), at 8.—A. M. Hocart: Caste in Fiji.
LEICESTER LITERARY AND PHILOSOPHICAL SOCIETY (Chemistry Section) (in College of Technology, Leicester), at 8.—Dr. G. Lawton: Some Metallurgical Problems in the Electrical Industry.
ELECTROPLATERS AND DEPOSITORS TECHNICAL SOCIETY (at Northampton Polytechnic Institute), at 8.15.—A. W. Hothersall: Some Investigations in Copper Deposition.
ROYAL SOCIETY OF ARTS, at 8.30.—Lt.-Gen. Sir William Furse: Some Aspects of Inter-Imperial Trade (Trueman Wood Lecture).
SOCIETY OF GLASS TECHNOLOGY (at Stourbridge).

THURSDAY, MARCH 19.

LINNEAN SOCIETY OF LONDON, at 5.—Prof. J. Stanley Gardiner: Photosynthesis and Solution in the Building of Atolls.—Dr. Max Bernhauer and Dr. H. Scott: Coleoptera, Staphylinidæ of Abyssinia.
ROYAL COLLEGE OF PHYSICIANS OF LONDON, at 5.—Sir William Willcox: Toxic Jaundice (Lumleian Lectures) (1).
ROYAL INSTITUTION OF GREAT BRITAIN, at 5.15.—Prof. J. B. S. Haldane: Respiration (3).
INSTITUTION OF MINING AND METALLURGY (at Geological Society), at 5.30.
CHILD-STUDY SOCIETY (at Royal Sanitary Institute), at 6.—Miss Marion Richardson: Children's Drawings.
ROYAL AERONAUTICAL SOCIETY (at Royal Society of Arts), at 6.30.—Dr. W. Hoff: Research in the Berlin Technische Hochschule.
ILLUMINATING ENGINEERING SOCIETY (at Institution of Electrical Engineers), at 7.—H. T. Young: Modern Domestic Lighting.
INSTITUTE OF RUBBER RESEARCH (at "Manchester Ltd.", Manchester), at 7.—S. A. Brazier: Some Problems in Sponge Rubber Manufacture.
SOCIETY OF CHEMICAL INDUSTRY (Bristol Section) (Annual Meeting) (at University, Bristol), at 7.30.—Chairman's Address.
CHEMICAL SOCIETY, at 8.—F. M. Rowe and A. T. Peters: A New Reaction of Certain Diazosulphonates Derived from β-naphthol-1-sulphonic Acid. Part IV. The Constitution of the Condensation Products of Diazo-compounds with β-naphthol Derivatives Substituted in the 1-position.—F. M. Rowe, Miss E. Levin and A. T. Peters: A New Reaction of Certain Diazosulphonates Derived from β-naphthol-1-sulphonic Acid. Part V. The 4-nitro- and 4′-amino-derivatives of 4-methyl-3-phenylphthalaz-1-one.—F. M. Rowe and C. Dunbar: A New Reaction of Certain Diazosulphonates Derived from β-naphthol-1-sulphonic Acid. Part VI. Preparation of Phthalazine, Phthalazone and Phthalimidine Derivatives from 2:6-dichloro-4-nitroaniline.—F. M. Rowe and N. H. Williams: A New Reaction of Certain Diazosulphonates Derived from β-naphthol-1-sulphonic Acid. Part VII. Preparation of Phthalazine, Phthalazone and Phthalimidine Derivatives from 2:6-dibromo-4-nitroaniline.—K. N. Menon and R. Robinson: Strychnine and Brucine. Part XII. The Constitution of Dinitrostrycholcarboxilic Acid.
ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE (at Royal Army Medical College, Grosvenor Road, S.W.), at 8.15.—Laboratory Meeting.
HARVEIAN SOCIETY OF LONDON (at 11 Chandos Street, W.1), at 8.30.—Sir Percy Sargent: The Romance of the Pituitary Gland.
BRITISH INSTITUTE OF RADIOLOGY (at 32 Welbeck Street), at 8.30.

FRIDAY, MARCH 20.

PHYSICAL SOCIETY (at Imperial College of Science) (Annual General Meeting), at 5.—Presentation of Duddell Medal, 1930, to Sir J. Ambrose Fleming.
ROYAL SANITARY INSTITUTE (at Technical College, Lincoln), at 5.—L. O. Need and others: Discussion on Houseboats on Inland Waterways.—S. C. Baggott and others: Discussion on Refuse Collection and Disposal.
ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Sir Arthur Keith: Demonstration of the Anatomy and Nerve Supply of the Diaphragm.
INSTITUTION OF MECHANICAL ENGINEERS, at 6.—R. S. Allen and W. E. W. Millington: Modern Methods of raising Water from Underground Sources.
NORTH EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (at Mining Institute, Newcastle-upon-Tyne), at 6.—T. Millican: Corrosion with Reference to Boilers.
INSTITUTION OF ELECTRICAL ENGINEERS (Meter and Instrument Section) (Informal Meeting), at 6.30.—W. Lawson and others: Discussion on Should the Bottom Bearings of Meters be Oiled?—W. Holmes and others: Discussion on Are Cobalt Steel Magnets Desirable for Use as Permanent Magnets for Instruments?—Lt.-Col. K. Edgcumbe and F. Hope-Jones: Discussion on Are Synchronous Motors or Clocks More Suitable for Time Service?—J. W. Record and W. Phillips: Discussion on Are Long Scales Preferable to Short in Indicating Instruments?
INSTITUTE OF CHEMISTRY (Manchester Section) (Annual General Meeting) (at "Manchester Ltd.", Manchester), at 7.—Prof. R. M. Caven: Lecture.
INSTITUTION OF ELECTRICAL ENGINEERS (Meter and Instrument Section), at 7.—Informal Discussion.
INSTITUTION OF MECHANICAL ENGINEERS (jointly with Institution of Automobile Engineers) (at Merchant Venturers' Technical College, Bristol), at 7.—Dr. J. S. Davies: An Experimental Investigation into Induction Conditions, Distribution and Turbulence in Petrol Engines.
SOCIETY OF CHEMICAL INDUSTRY (Newcastle Section) (at Armstrong College, Newcastle-upon-Tyne), at 7.30.—H. W. Howes: Pyrex Glass, its Properties and Application.
JUNIOR INSTITUTION OF ENGINEERS, at 7.30.—W. S. Roberts: Some Token Systems of Railway Signalling.
ROYAL SOCIETY OF MEDICINE (Electro-Therapeutics Section), at 8.30.—Dr. Chalmers Watson: Radiation in Relation to Human and Animal Life.
ROYAL INSTITUTION OF GREAT BRITAIN, at 9.—Prof. E. N. da C. Andrade: Sound, Sand, and Smoke: New Light on Old Problems.
GEOLOGISTS' ASSOCIATION (North-East Lancashire Group) (at Technical College, Blackburn).—J. Ranson: The Structure of the Alps (Lecture).

SATURDAY, MARCH 21.

INSTITUTION OF MUNICIPAL AND COUNTY ENGINEERS (Yorkshire and North Western Districts) (at College of Technology, Manchester), at 2.30.—Dorman Long and Co., Ltd.: The Building of the New Tyne Bridge; The Building of Imperial Chemical House; and The Sydney Harbour Bridge.
MATHEMATICAL ASSOCIATION (at Bedford College), at 3.—S. Inman: Contracted Methods in Arithmetic.
ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Lord Rutherford: Recent Researches on the Alpha Rays (3).

PUBLIC LECTURES.

FRIDAY, MARCH 13.

BRITISH MEDICAL ASSOCIATION (Tavistock Square), at 8.—Prof. E. Mellanby: Diet and Health (Sir Charles Hastings Lecture).

SATURDAY, MARCH 14.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—D. Martin Roberts: London in the Augustan Age.

MONDAY, MARCH 16.

KING'S COLLEGE, LONDON, at 5.30.—Prof. K. S. Lashley: Problems in the Physiology of Behaviour. (Succeeding Lectures on Mar. 18 and 19.)
UNIVERSITY COLLEGE, at 5.30.—Prof. B. Brouwer: The Central Nervous System. (Succeeding Lecture on Mar. 17.)

TUESDAY, MARCH 17.

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL, at 5.15.—Dr. C. H. Andrewes: Immunity in Virus Diseases (1).

WEDNESDAY, MARCH 18.

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE, at 5.—Lt.-Col. G. E. F. Stammers: Tropical Hygiene for Men and Women proceeding to the Tropics. (Succeeding lectures until Mar. 27.)
KING'S COLLEGE, LONDON, at 5.30.—Dr. V. T. Harlow: The Great Age of Discovery: The Search for El Dorado.

FRIDAY, MARCH 20.

INSTITUTION OF PROFESSIONAL CIVIL SERVANTS (at Chartered Surveyors' Institution), at 5.30.—C. S. Wright: The Scientific Purposes of Antarctic Exploration.

SATURDAY, MARCH 21.

HORNIMAN MUSEUM (Forest Hill), at 3.30.—J. E. S. Dallas: Peasant Life in Alpine Districts.

SATURDAY, MARCH 21, 1931

The Study of British Archæology

ARCHÆOLOGICAL studies, like many other things, have changed greatly since the War. They have now passed definitely and finally from the province of the antiquarian and the dilettante. In Great Britain, science, at least in certain of its branches, has always been the playground of the amateur; and archæology perhaps more than any other of these studies, except perhaps astronomy, owes much to his efforts. But long before the War it had been made evident that archæological exploration demanded more than merely the opportunity and the means—for digging is an expensive business—to open up a burial mound or a prehistoric settlement. It needs but a glance through the pages of an archæological publication with a long run, such as *Archæologia*, for the last thirty or forty years, to appreciate the vast amount of excellent work that has been done in Great Britain on thoroughly sound lines by men who were scientific in method if in status they were amateur.

Excellent as this work was, too often its outlook was restricted and its interest confined to one aspect or to one type of problem. To-day, it may seem scarcely credible that in the last decade of the nineteenth century the British Association appointed a committee to ensure the record and preservation of objects not of Roman or Romano-British origin found in the excavation of Romano-British sites in Britain. In spite of the interest that has been taken in Roman antiquities in Britain—an interest which has been alive literally for centuries—we still know little of the relation of British settlement and Roman site—less indeed than of almost any other question in British archæology; and it is only now that investigations at St. Albans, Colchester, Llanmelin, and one or two other sites are gradually accumulating the needed evidence. In some phases of prehistoric archæology the available material along certain lines is plentiful; along others, certainly of no less importance, it may be scanty, or even entirely lacking.

It is not without significance that archæologists are now prone to speak of 'prehistory', perhaps even more than they use the term 'prehistoric archæology'. The change may be one of orientation only; but it is a change which carries with it many implications. The view has become broader. It is no longer adequate to study a site *per se*, to assign it to its period, or even to seek analogies of detail elsewhere. The prehistorian must look to its geographical and cultural relations, and his aim is rather to assign it to its proper place as an

index of cultural development and movement His method is synthetic rather than analytic

This change in point of view in the study of British archæology to day was foreshadowed before the War So long ago as the beginning of the present century, Lord (then the Hon John) Abercromby in his studies of bronze age pottery combined a detailed examination of form and ornament with a broad view of distribution and the inferences to be drawn therefrom as to cultural and racial movement, a piece of work which for many years had a marked effect on the work of British archæologists and of which the full force is not yet spent

At the same time, in the study of archæology, or rather prehistory, on the Continent, beginning with the Mediterranean area, much attention had been devoted to questions of distribution, interrelationship, and cultural and racial movement In these studies, British archæologists had no small share, but when they turned to their own country, in working out their problems, they found lamentable gaps in the evidence questions of distribution had scarcely been attacked, and there had been but few attempts to co ordinate information A recent writer has directed attention to how little, relatively, is really known of the Iron Age in Britain

Fundamentally the problem, to a great extent, is one of distribution A great advance was made immediately after the War by the appointment of an archæological officer to the staff of the Ordnance Survey Department This has assured greater attention and care in the recording of certain classes of antiquities, but the real need is for a whole series of maps recording the location of all classes of antiquities This covers only what is already known How much may yet remain to be dis covered is incalculable, but the aeroplane has revealed possibilities To it we owe Woodhenge Here the aeroplane brought to the knowledge of the archæological world a new and unsuspected type of prehistoric monument, and this is one only of the discoveries for which we are indebted to the Royal Air Force Within the last few days, aerial photographs taken in the course of military exercises have revealed four previously unknown temporary camps along the line of Hadrian's Wall between Wallsend and Gilsland, and indications at Housesteads and Chesters point to civilian settlement of a size and plan not previously suspected More important in the present connexion is it that these photographs suggest the lines of future re search Is it too much to suggest that training for the Royal Air Force in air photography, which can be carried out anywhere, might be combined with a systematic archæological survey of the country?

It requires no more than a superficial view of the present situation of archæological studies in Great Britain to see that the need of the moment is synthesis and organised research—investigation along lines on which information is least adequate This involves a mobilisation of information and co operation between the various archæological interests throughout the country In Northern Ireland, as noted elsewhere in this issue, a movement has been initiated to record all ancient monuments within a certain area, with all obtainable information concerning them Similar records for England, Scotland, and Wales are eminently desirable They would form an admirable basis for the fuller archæological survey which we feel a necessity for any real advance in archæological studies In the meantime, the Congress of Archæological Societies has published the first report of its Research Committee, which was appointed in 1929 We commend this most valuable document to all who are interested in archæological studies, for the Committee, in advocating a policy of cooperation and organised research, has enumerated for each period of prehistory the problems which it will be the task of research to solve

The New Survey of London

The New Survey of London Life and Labour Vol 1 *Forty Years of Change* Pp xv + 438 (London P S King and Son, Ltd, 1930) 17s 6d

THIS continuation of Charles Booth's Survey of London, of forty years ago, has everything to commend it The new editor-in-chief, Sir Hubert Llewellyn Smith, quotes very aptly from Charles Booth on his title page "Comparisons with the past are absolutely necessary to the comprehension of all that exists to day, without them we cannot penetrate to the heart of things" The original Survey, which began to appear in 1889, was the work of one rich, enlightened, and benevolent man It has now been taken up again by a combination of public bodies, centring in the London School of Economics, and under the direction of the sometime Permanent Secretary of the Board of Trade The change is significant of the vast advance in organisation and socialisation which has taken place in the interval This introductory volume testifies to many other changes in the life of the people of London, and the pleasantest thought, after reading it, is that, on the whole and in almost every

measurable aspect, the people of London are better off than when Charles Booth first surveyed them

The various signs of this improvement, and the fundamental causes for them, are, as we might expect, either directly scientific or akin to science We may distinguish three or four First, the increase in organisation and its better direction to social ends Allied with this must be mentioned the organisation of the workpeople, which has been the chief agent in securing their substantial rise in wages Next must be placed medical and sanitary science, which has in the period made London by far the healthiest of the great cities of the world Lastly—put first in importance by some of the contributors to the volume—comes the general elementary education of the people, which has been successfully enforced by an admirable civic organisation So successful has this been that for the most part compulsion is now unnecessary, both parents and children now accept the school law as part of the law of Nature, and the latter are enthusiastic about it

On each of these aspects a few words may give some idea of the contents of this most carefully executed and inspiring volume

Organisation, especially as applied to transport, is probably the factor which has made the most palpable change in London in the forty years Our whole present system of underground trains, with electric buses and trams, has been evolved in this time It is the best in the world, and has altered the conditions of life more than any other single factor Quicker transit, over longer distances, has taken the bulk of the population into fresher air and less crowded surroundings The change has also opened the eyes of the public to the intolerable legacy of the slums which remain

The rise in wages and the lowering of hours of work are treated in great detail and with strictly corrected statistics Broadly speaking, and allowing for the rise in the cost of living, the workmen of London are 30 per cent better off than when the first Survey was published, and they gain this 30 per cent for a working day of about an hour less in duration The so-called 'unskilled' have gained proportionately the larger part, but the advance is general

The use made of this increased leisure and means is treated rather summarily in this introduction, and we shall look for a more thorough account later on But on two other aspects the reporters are emphatic These are health and education The improvement in public health is so remarkable that we must give a few of the figures Since 1880 the death-rate per thousand has been nearly halved, having gone down from a little more than 20 per thousand to a little less than 12 In the case of infants, the decrease is far greater, for the death-rate per thousand for them was in 1880 about 150, and had been more, while in the latest returns included in this book it has fallen to 68 Dr Wheatley, who is quoted on this subject, attributes the improvement mainly to the growth of an educated public opinion "The saving of child-life came about as soon as a generation which had passed through the primary schools had become the parents of a new generation" No doubt the accompanying fall in the birth rate accounts for a good deal in this result Having fewer children, mothers are freer and more determined to take the utmost care of those they have But it is shown by the statistics that the improvement had begun before the fall in the rate, and many points in child welfare have been sedulously inculcated in recent years by all sorts of beneficent organisations outside the schools

If one is to criticise at all, it would be that the reporters are inclined to be somewhat too optimistic with regard to the level of education and the direct result of school-teaching Two of their conclusions suggest this remark One is the statement, sometimes explicit and oftener implied, that we have now achieved an 'educated' population in London, if not an educated democracy as a whole This surely puts the advance far too high A special inquiry, as careful and expert as this, into the education of the people of London would be a valuable and enlightening thing It would, one fears, lead to a rather less roseate picture than is given of the definite and measurable improvements in health, wages, and transport Connected with this point, one is inclined to surmise that the great improvement in the mortality statistics is more largely due to better sanitation and health administration, as well as the rise in the standard of living, than to the education provided by the schools But the subject obviously is a very complicated one, and no one would wish to lessen the credit due to the teachers and to the education service generally, which, as organisation, is perhaps the most admirable thing which Great Britain has carried through in the time of this review

Three blots disfigure the otherwise bright tableau which is unfolded One, the most conspicuous, is what is commonly known as 'Poplarism' Entirely within this period, the habit has grown up in certain large areas, both in London and elsewhere, of treating poor law relief as an habitual resource, in place of, or in supplement to, wages The

growth of this evil and the recent efforts to stem it are faithfully described The second, less rampant, but significant and disturbing, is the increase of certain classes of sexual offences amid a general and very considerable fall in crime The third, directly connected with the growth of motoring and possibly with the employment of the police in controlling motor traffic, is an increase in burglary—not, as is sometimes supposed, in the London area itself, but in the surrounding belt which may be reached, raided, and left by the motor bandit This is one of the incidentals of a scientific advance, and still leaves us well behind Chicago

F S MARVIN

The Life-Work of Francis Galton

The Life, Letters and Labours of Francis Galton By Prof Karl Pearson Vol 3*a* *Correlation, Personal Identification and Eugenics* Pp xiv + 440 + 44 plates Vol 3*b* *Characterisation, especially by Letters Index* Pp vi + 441 673 + 18 plates (Cambridge At the University Press, 1930) 69*s* net

THE completion of this great " Life " of a great man is an achievement, and we wish to express what all interested must feel, that the library of science has been enriched in a very noble way We venture to congratulate Prof Karl Pearson on the success of his undertaking , he has given us a painting by a master No doubt it has been a labour of love and not without the artist s joy , but it has meant many years of strenuous sifting and appreciating and arranging to elaborate this worthy record of the life and work of one of the most notable pioneers in the history of civilisation Therefore, if we may be a mouthpiece, we would simply thank Prof Pearson for this monumental work, surely never excelled in completeness, accuracy, insight, and keen judgment flashing like a two-edged sword We have to congratulate our science that such a biographer was available and willing, for no one else could have summed up Galton's labours with such competent authority or pictured the man with such sympathetic understanding

On the whole, we suppose, we should be glad that it has been possible to complete the work on the same grand scale throughout , and it is something to be proud of that wise generosity has helped to make it possible In these two concluding parts (vols 3*a* and 3*b*) there are 673 pages and 59 plates, besides beautiful frontispieces—the whole a great credit to the Cambridge University Press The volume is expensive , but good value for the money What the biographer says in this connexion is of refreshing interest He points out that he has devoted to his task much of his time for twenty years, and that he made up his mind from the outset that the biography should be done to satisfy himself and without regard to traditional standards, to the needs of publishers, or to the tastes of the reading public " I will paint my portrait of a size and colouring to please myself, and disregard at each stage circulation, sale or profit " There is a delightful breeze about this—a suggestion of one of the great masters , and the publication has been accomplished Our only regret is that the price of volumes so monumental and magnificent is prohibitive for most of us—especially perhaps for those with youth on their side, who are naturally attracted to new movements, such as the one to which Galton gave so much of his pioneering energy

The biographer's second reason for being anything but apologetic for the size and splendour of his volumes is that it seemed to him well worth while to gather together, once for all, everything that contributed towards a complete appreciation of Galton's labour and thought In a short time, verification becomes difficult and documents disappear , so Prof Pearson resolved to preserve in permanent form all that is essential ' In the centuries to come, when the principles of eugenics shall be commonplaces of social conduct and of politics, men, whatever their race, will desire to know all that is knowable about one of the greatest, perhaps the greatest scientist of the nineteenth century " So be it, and their gratitude will be added to ours What is needed, however, since these dignified volumes are frankly too expensive for first class minds with third-class purses, is the preparation of a relatively small volume, like the recently published admirable appreciation of Erasmus Darwin, available to all who wish to learn what this great life has to teach , and if the veteran biographer cannot do it himself, he has not to look far for one who can

In vol 3*a* we find (1) an account of Galton's work on correlation and the application of statistics to the problems of heredity , (2) a discussion of what Galton did with reference to finger prints , and (3) the story of the last decade of his life and the concentration of his many endeavours to make eugenics an ideal for educated men and women Vol 3*b* is devoted to characterisation, especially by means of letters Both volumes are generously and beautifully illustrated

We wish to refer briefly to a question of terms used in reference to eugenics If eugenics be " the study of those agencies which under social control

may improve or impair the racial qualities of future generations either physically or mentally it does not seem to us that anything is gained by calling it a creed still less a religious faith But Galton was very strongly of the opposite opinion He considered various definitions and affirmed that the direction of the emotions and desires towards a furtherance of human evolution recognised as rightly paramount over all objects of selfish desire justly merits the name of a religion His biographer corroborates this usage for he writes

Man has learnt how to breed plants and most inferior forms of life that are of service to him He has yet to learn how to breed himself When he has studied heredity and environment in their influence on man the application of the laws thus found to the progressive evolution of the race will become the religion of each nation Such is the goal of Galtonian teaching the conversion of the Darwinian doctrine of evolution into a religious precept a practical philosophy of life Is this more than saying that it must be the goal of every true patriot ? This last question hits the nail on the head The eugenic ideal of improving the human breed is a goal an aim an ambition but it is scientific not religious There is nothing mystical about it as there is in all religious activity according to the great majority of its competent students We should not have lingered over this point did not the usage sanctioned by Galton and Pearson both so nearly perfect in precision seem to us to be somewhat of a hindrance to the diffusion of the eugenic ideal or aim That the eugenic endeavour should come to have an intensity comparable to that of a high religious aspiration is indeed our hope and prayer but that is not the question before us

As we read the story of Galton s life and labours and recall what we read in the previous two volumes a good many years ago we cannot repress a feeling of almost embarrassing admiration For Galton was a genius in the sense that he had abilities of unique pattern and at a high power of intensity yet all regulated by indefinable wisdom by magnanimity and by a great kindliness Having had unforgettable experience of this characteristic kindliness we can understand in some measure the feelings of those who stood around Galton s grave in Claverdon churchyard in January 1911 What we felt deeply was the personal loss of that gentle affectionate and modest nature generous in thought and in practice here bestowing an idea and there a helpful hand rarely saying a harsh word and often moderating the acerbity of others taking life earnestly, but with a saving sense of humour he would have been of earth s elect even if he had never achieved high rank in science It was the loss of that ever flowing spring of understanding human sympathy that we felt most bitterly What an outstanding argument for eugenics the man was !

On those qualified to judge Galton s work has left the impression of a mind of the first rank and there was a characteristic freshness retained throughout life which enabled him to illumine whatever he touched We must think of his contributions to medicine evolution anthropology geography psychology heredity and statistics—showing a marvellous many sidedness To this quality so convincingly documented in these volumes the biographer playfully referred when he took the chair at Galton s famous address to the Sociological Society in 1904 on Eugenics its Definition Scope and Aims If I wanted to know how to put a saddle on a camel s back without chafing him I should go to Francis Galton if I wanted to know how to manage the women of a treacherous African tribe I should go to Francis Galton if I wanted an instrument to measure a snail—or an arc of latitude—I should appeal to Francis Galton If I wanted advice on any mechanical or any geographical or any sociological problem I should consult Francis Galton And it was not in the least that he was an incarnated encyclopædia it was rather that he had unusual fertility lucidity and elasticity of mind—an ever youthful mind save that it grew wise

It is not for us to pay compliments to the distinguished continuator of the work of a great initiator but in our position for the moment as reviewer we must be allowed to express our admiration at the perspective and proportion that mark these volumes Amid the manifoldness of recorded achievement there is no crowding or jumble and this is the reward granted to an artist who mixes his paints with brains There was a unity underlying all Galton s varied work which only reveals itself when after much inquiry and retrospection we view it as a whole and with a spirit trained to its modes of thought Twenty years of almost continuous reflection on Galton s labours have enabled me to see using his own words the whole as a permanent panorama painted throughout with equal colours and to grasp better how great diversity of production may nevertheless be consistent with a marvellous unity in the main aim of a life For the dominant and unifying idea of Galton s life s work was to measure the influence of heredity on the mental and physical attributes of mankind in order that a true knowledge of natural

inheritance might enable man to lift himself to a loftier level"

In our judgment, Francis Galton should be for ever memorable (1) as a vindicator of the rôle of statistics (in the broad sense) as an organon of research, and (2) as one of the three founders of the science of heredity Darwin had indeed shown that the facts of heredity are amenable to scientific treatment, but the three men who laid the foundation-stones of genetics—the science behind eugenics—were Galton, Mendel, and Weismann, each with his characteristic contribution—biometric, experimental, and cytological respectively It is, of course, of great interest that while Weismann's work was quite independent, it was anticipated by Galton in its idea of the continuity of the germ-plasm (which the biologist of Freiburg *demonstrated*), and in its scepticism as to the transmissibility of acquired characters Galton and Mendel were both born in 1822, Weismann's year was 1834 We believe we had the honour of directing Weismann's attention to Galton's earliest papers, of which he was unaware, and at that date neither of them knew anything about the lamentably well hidden treasure of Mendelism It meant a retardation of progress that the three foundation layers were independent contributors rather than co-operators, but this has happened repeatedly in the history of science

But what was Galton's chief service to mankind? It was not exactly the new method of biometry nor the scientific foundation he gave to the study of heredity It was not even his vision of eugenic possibilities, for though this was fuller and clearer to Galton than to any previous investigator, the eugenic ideal of having a fine family is one of the oldest ambitions in the world Galton's greatest service was in being a pioneer in thinking of man biologically Just as Darwin, his great cousin, discovered man as an evolved species, solidary with the rest of creation, so Galton saw man as a species evolving, and if evolving, then with a progress and retrogress that can be more or less understood, and thereby more or less controlled By application of biological laws, man may learn to breed himself as he breeds his crops and stock, though to even finer issues That was the new idea, the new hope, the *novum organon*—to use science for life, man must learn, in Pearson's fine phrase, "to tame by science the nescient waywardness which lays waste his stock" He has learnt not a little in the moment of time since Galton died, thanks to the eugenics laboratory on one hand and eugenics societies on the other, which ought to work in the heartiest co-operation, and he will learn more rapidly whenever he cares more about it Heaven forfend that he should learn too late, for that would be the grimmest of all ironies

If man is to control his own evolution in the light of science, he will need all the science he can get—not of heredity alone, but also of functioning and environment as well, eutechnics and eutopias as supplements to eugenics Since the organism is a unity, the aid of eupsychics must be also invoked, and of moral education too, even more than Galton would admit As sociologist, Galton was more or less free from the biologisms which take the pith out of many eugenic endeavours for it is a terrible fallacy to ignore the differentiating 'social heritage', which is as supreme as Galton's 'natural inheritance' is fundamental Moreover, we often wonder whether the outlook of initiator and continuator alike might not have gained by recognising that we need in our eugenics more than *human* biology For in the animal world there have been eugenic achievements strongly suggestive of heights to which man, usually so badly shackled and enmeshed, has not as yet approached But that is another story!

Galton has been well called "a *religious* agnostic", and here the word religious is used in its proper sense, to indicate the sending forth of tendrils towards the Supreme Reality "Galton believed in a recondite purpose in the Universe, which we men cannot unriddle, and he urged his fellows with religious earnestness to take up the burden of their task and further develop their species in fitness to its environment Increased vigour of mind and body appeared to him the aim of the power which we seem to discern working obscurely, and as if with difficulty, behind the apparently blind Forces of Nature" *In hoc signo laboremus*

Liberia and the Belgian Congo

The African Republic of Liberia and the Belgian Congo based on the Observations made and Material collected during the Harvard African Expedition, 1926–1927 (Contributions from the Department of Tropical Medicine and the Institute for Tropical Biology and Medicine, No 5) Edited by Richard P Strong In 2 volumes Vol 1 Pp xxvi+568 Vol 2 Pp ix+569-1064 (Cambridge, Mass Harvard University Press, London Oxford University Press, 1930) 67*s* 6*d* net

DR R P. STRONG states in his introduction that the Harvard African Expedition of 1926–27 was planned, first, for the purpose of

making a biological and medical survey of Liberia, the interior of which even now, although within twelve days of Great Britain, is, as Sir Harry Johnson stated in 1906 in his book "Liberia", still the least-known part of Africa, and secondly, to cross the continent from west to east, travelling particularly through the Belgian Congo After the survey of Liberia was completed, the expedition proceeded by sea to the Congo and up that river to Stanleyville, continuing up the Lualaba to Kabalo, then eastward to Albertville on Lake Tanganyika, afterwards travelling northward via the Lakes Rift, and eventually reaching Mombasa by way of Lake Victoria and Nairobi

The first 200 pages of vol 1 of this wonderfully well got up and beautifully illustrated book, dedicated to Mr Harvey S Firestone, are of special interest, being devoted exclusively to the Black Republic, its climate, inhabitants, agriculture, medical and social conditions, and its natural history There are also chapters dealing with slavery and maladministration in the hinterland of Liberia which afford ample confirmation of the findings of the recent International Commission of Inquiry Dr Strong writes in relation to the periodic tours in the interior, of the Commissioner-General and the major commanding the frontier force, who are usually accompanied by a large number of soldiers, messengers, and others

"Official regulations require the natives of the hinterland to furnish porters for the government The porters receive no pay After these visits the towns or villages are frequently left in at least temporary destitution, for apparently almost everything of value is taken away Goats, poultry, and other food supplies, the few animal skins or articles of native manufacture in the town, and sometimes even the young or more attractive girls, disappear There is no redress for this extortion To avoid it, villages are sometimes abandoned and groups of natives abscond across the border, not always to return This practice of raiding by the District Commissioners, however, has become more or less known In 1926 the Liberian legislature made an investigation, in which two aboriginal native Commissioners (not Americo-Liberian) were concerned It disclosed the fact that in the name of providing entertainment for the President, who was making a tour of the hinterland, several native Commissioners had collected from the natives, without payment, about 200 goats, 585 hampers of rice, 40 tins of palm oil, 400 chickens, and other articles of food, to the total value of $1600 Although the President found it impossible to visit the area, the Commissioners kept the food After the investigation, the House of Representatives passed a resolution asking that the salary of one of the Commissioners he withheld until he returned the articles *to the government*, and that the other Commissioner be dismissed Obviously, however, it is exceptional to make any excuse, such as a possible visit of the President, for such raids upon the villages"

The book is first and foremost a valuable addition to our general and detailed knowledge of the diseases of tropical Africa, west coast and central Africa in particular, their causation and transmission, as well as their histological pathology—for since the expedition returned to America a vast amount of work has been done on the material that was collected Malaria, the most prevalent of all diseases in the tropics, and of the first economic importance, is dealt with mainly in relation to the incidence of infection in various localities The routine malaria work carried out during the progress of the expedition affords some interesting results "Almost no one", state Drs Strong and Shattuck on p 212, vol 1, "doubts the value of the splenic index as affording a simple and rapid method of estimating the degree of malaria in some infected areas, but on the other hand it certainly does not furnish means of discovery of all malarial infections, and it would be exceedingly unwise in certain tropical districts to assume that all cases of splenomegaly are necessarily malarial in origin"

Much of the recent work on splenomegaly is summarised, yellow fever, filariasis, and other mosquito-borne diseases are usefully discussed, and again much of the recent work on these diseases is summarised for the student During the course of the investigations in Liberia, some discoveries were made in connexion with *Onchocerca volvulus* and *Simulium damnosum*, the large black, white-footed simulium known as the 'Jinja fly', first named by Theobald from specimens collected at Jinja, near the Ripon Falls, by the reviewer, whose description of the sanguinary appearance of the bare legs of his tormented porters on the Jinja-Kampala road inspired the name *damnosum* The Harvard Expedition's observations with reference to *Simulium damnosum* as the transmitter of *Onchocerca volvulus* are apparently the first to confirm the very important ones of Blacklock published a few months previously The discovery of the relation of onchocerciasis to keloid formations and juxta-articular nodules is also of importance Much space is given to yaws and syphilis, and many interesting photographs of cases met with are shown

Though well known to the natives of the interior, human trypanosomiasis—sleeping sickness—was found to be rare in Liberia, only five cases of

trypanosomiasis being discovered, all from one district, although *Glossina palpalis* was common, and in only one tsetse fly were trypanosomes detected Animal trypanosomiasis was also found to be rare in Liberia In the Congo, of course, conditions were very different, and more space is devoted to the subject in dealing with that region

In Chap xxvi we find useful information on economic plant diseases No infectious disease, however, was found to affect the oil palm which is extremely common in Liberia, much more so than in the neighbouring protectorate of Sierra Leone, and should be of great commercial importance The question of whether monkeys may act as hosts for the malaria parasites of man is considered in Chap xxvii, and the reader will experience a sense of relief at the realisation that there is still no evidence that malaria can be transmitted from the apes to man, although plasmodia, in some cases indistinguishable under the microscope from malaria parasites in the blood of man, are not uncommon in both monkeys and the apes Beautiful coloured illustrations of these latter protozoa are given in Chap xxx

An interesting botanical report of Liberia, with some very good reproductions, concludes vol 1

Vol 2 deals with the mammals and birds of Liberia, birds collected in the Belgian Congo, and medical and economic entomology It does not contain merely lists of specimens obtained on the expedition and descriptions of new species, but also aims at mentioning all the species hitherto collected from this region, thus enhancing the value of the work from the systematic point of view

C Christy

Our Bookshelf.

Die Rohstoffe des Tierreichs Herausgegeben von Ferdinand Pax und Walther Arndt Bd I, Lief 4 Pp 161-320 12 75 gold marks Lief 5 Pp 321-448 12 gold marks (Berlin Gebruder Borntraeger, 1930)

The first 48 pages of the fourth part of this work contain the concluding portion of the chapter on fats, and deal with (1) the occurrence, extraction, characters, and use (largely as the basis of cosmetics) of spermaceti, (2) the animal fats employed with vegetable fats in the manufacture of soap, (3) ox-gall and its uses in industry, chiefly in colour work, and (4) fossil bitumina, including asphalt and petroleum

The remainder of the fourth part and the whole of the fifth are devoted to a consideration of the skins and membranes of animals used in commerce Accounts are given of hides and the modes of drying them, and of the chief methods of preparing leather The nature and varied uses of the skins of elasmobranch and other fishes and of reptiles and birds are described Reference is made to the damage caused by 'warbles'—the larvæ of *Hypoderma*, which in Germany in 1929 was estimated to amount to nine million marks Short accounts are given of the uses of leather in ancient and in medieval times, and of the present usage of leather by natives in different parts of the world, and a note is added on leather money,

The section on the preparation and usage of membranes derived from internal organs shows what each part of the alimentary tract—œsophagus, stomach, small and large intestine—yields in commercial products Here is found information on the preparation of goldbeater's skin, usually made from the outer layer of the cow's cæcum, of catgut, now made from the small intestine of the sheep, and of the coverings for the vast quantity of sausages consumed, especially in Germany and Austria

The final chapter, on furs, opens with a description of the different types and arrangement of hair, and the successive changes in the hair and its colour during the growth of the animal This is followed by an account of the North American and Russian fur trades A survey (unfinished) of the principal furs of commerce is arranged in systematic zoological sequence, beginning with the Monotremes

These parts present a compact source of information which is rendered readily accessible by the use of subheadings in heavy type In each section, historical data are given, and a bibliography is appended

Determination of Orbits of Comets and Asteroids By Prof Russell Tracy Crawford Pp xi + 233 (New York McGraw-Hill Book Co, Inc, London McGraw-Hill Publishing Co, Ltd, 1930) 20*s* net

In Nature, July 14, 1928, a note appeared on the second (reset) edition of Bauschinger's "Bahnbestimmung der Himmelskörper", with an appeal for an English translation Bauschinger's treatise, however, had not been brought up to-date since its first appearance in 1906, and was expensive (£3) These defects were remedied a year later in a volume by Stracke, of the Rechen Institut in Berlin, which dealt with modern methods (except Leuschner's) including their adaptation to calculating machines But there has been no text-book in English since Watson's "Theoretical Astronomy" in 1867 Prof Crawford has now filled this gap in our literature In order to keep his book within the bounds of a university text book that can be mastered in a one year's course, Prof Crawford has assumed a working knowledge of spherical astronomy He develops his subject concisely, and leaves the more difficult subjects of perturbations and definitive orbits for later and more specialised study The two methods described are a modern adaptation of Laplace's by Leuschner, and a recent modification of Gauss's by Merton The former is the favourite method in America, but it has never been taken

up by anyone who has not been to Berkeley and studied under Leuschner himself The latter is a modernised version of the methods in vogue on the Continent and it is unlikely that it will yield on this side of the Atlantic, to Leuschner s method It offers more straightforward processes and greater facilities for checking at each stage

The first three chapters by themselves enable a computer to prepare an ephemeris of a body from its known elements and also to comprehend fully the motion of a body moving under a central attraction The tables that accompany the work are printed with flat figures American printers have not yet realised that head and tail figures only are used in the best tabular productions Otherwise the book is well printed and it will certainly be welcome wherever English is spoken L J C

Religion and the Reign of Science By F Leslie Cross (Anglican Library of Faith and Thought) Pp x + 111 (London New York and Toronto Longmans Green and Co Ltd 1930) Paper 2*s* 6*d* net cloth 4*s* net

MR CROSS is inclined to think that the religion and science controversy has lost interest and that this is due to a prevailing scepticism which is having a disintegrating effect upon culture in general People have certainly turned away from the older type of apologetic but they are still interested in trying to see how scientific theories affect their philosophy of life and Mr Cross s book should help them to form intelligent opinions here He points out that the development of science has led to an increase in the range of casual determination but a decrease in that of final determination Everything had its cause but nothing its reason Not only miracles and prayer but even human freedom seemed altogether ruled out

Mr Cross holds that the question of freedom is more important for religion to day than the question of miracle The unbelieving multitudes to day are little helped by miracles and he gives a very able summary (pp 30 and 31) of the bearing of recent physical theories upon the problem of freedom He is not guilty however of trying to exploit the new physics in the interests of theological theory and warns us that the views of such thinkers as Whitehead Eddington and Jeans are highly individual and have received little assent from the learned world This is a very competent and useful book

The Archæology of Kent By R F Jessup (The County Archæologies) Pp xiv + 272 + 13 plates (London Methuen and Co Ltd 1930) 10*s* 6*d* net

IF London justly holds first place in the County Archæologies on the ground of its historic importance Kent is no less entitled to the second place for its archæological interest It is a county peculiarly rich in relics of the prehistoric and early historic periods It was in its plateau gravels that Benjamin Harrison found the famous eoliths over which controversy is not yet stilled Kit s Coty House and Coldrum are amongst the most interesting of our megalithic monuments and in Richborough which for some years has been under excavation by the Office of Works and the Society of Antiquaries it possesses a site which was in occupation by the Romans for practically the whole of the period of their stay in Britain Its Saxon relics are no less interesting for the light they throw on the relations of Kent both with the Continent and the rest of England The evidence for the various periods is passed in review by Mr Jessup but his account of Kent in the neolithic bronze and early iron ages will be particularly appreciated as this is the first time that the detailed evidence has been brought together His treatment of eoliths may appear a trifle over cautious and it would have been an advantage had he dealt more fully with the physical characters of the various races who settled in the county

Insomnia an Outline for the Practitioner By Dr H Crichton Miller Pp xi + 172 (London Edward Arnold and Co 1930) 10*s* 6*d* net

DR CRICHTON MILLER who is the director of the Tavistock Square Clinic is to be congratulated on his book on insomnia It is probably the best book on the subject It is not too long and is extremely well set out The author has not shown any hide bound prejudices and treats each case strictly on its merits In so many cases there is an emotional factor at work and until this is satisfactorily dealt with it is quite useless giving drugs and trying to cure the insomnia In the chapter on the psychological aspect of insomnia the various views on the conflict of life are placed before us In this chapter Dr Crichton Miller is careful to point out that Jung s views are more philosophical than scientific he is at heart a mystic The chapters on general treatment and medicinal treatment are good although we would like to see psychotherapeutic nurses have a training of twelve months in a mental hospital not three to six months !

Vorlesungen über Wellenmechanik gehalten an der Staats Universitat zu Columbus U S A Von Prof A Lande Pp iv + 132 (Leipzig Akademische Verlagsgesellschaft m b H 1930) 9 50 gold marks

THESE lectures are more in the nature of comments on wave mechanics than a formal treatment This is especially true of the first three sections on waves and corpuscles the uncertainty principle and quantum statistics in which the points of similarity and dissimilarity between the old and new ideas are brought out with great clarity Under the second head Prof Lande gives a neat derivation of the number of degrees of freedom in a system of stationary waves taking as fundamental the conception of cones of radiation a method usually explicitly avoided in this connexion The remainder of the book contains an outline of the applications of wave mechanics on more stereotyped lines and includes accounts of the derivation and applications of the simple wave equation the wave mechanics of systems undergoing temporal change and relativistic wave mechanics

Phenomena in a Sounding Tube

FROM the recent papers by Mr P S H Henry [1] and others, it appears that interest is being taken in the phenomena which occur in a sounding tube It may be well to direct attention to some results I have obtained, publication of which will shortly take place, having been delayed by illness

Direction of circulation at the centre→

Node Direction of circulation at the wall← Antinode

FIG 1 -Node to antinode circulation in dust free air

There are two main phenomena which have been hitherto undetected in experimental work on Kundt's tube, one of which takes place in the absence of all dust and is a free circulation of the air, while the other is caused by the presence of dust particles In general particles of dust of the size and mass used are much too massive to act as tracing points for the air motion, but behave rather as obstacles over which the vibrating air washes, although they may partake to some extent of the motion Particles of smoke, however, can be shown to take up the full motion of the vibrating air for ordinary acoustic frequencies, although with supersonic frequencies they do not, a point on which investigations are being carried out here At a frequency of 1200 per second, for example, the ratio of the amplitude (or velocity) of the smoke particle to that of the air is 0 9996

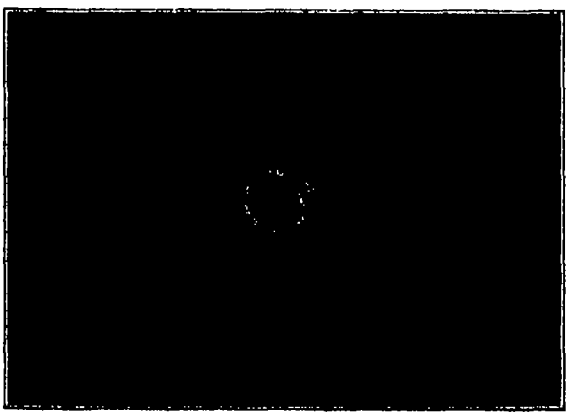

FIG 2 —Vortex system formed round a sphere by vibrating air The obstacle has been emphasised otherwise the picture is an untouched print The vertical band extending above the obstacle is a shadow, not a material bar

Using smoke in a tube containing air set in vibration by a valve maintained diaphragm[2] a perfectly regular circulation of air, from antinode to node along the walls and returning down the centre of the tube, has been detected The nature of the circulation can be clearly seen from the photograph reproduced in Fig 1, which represents part of a long tube of 3 5 cm diameter, the wave length being 56 6 cm A circulation of this kind was predicted by Lord Rayleigh,[3] who believed that something of the kind had been seen by Dvorak What Dvorak saw, however, was a motion of large particles of quite a different nature, as will be made clear in the forthcoming publication The lines of flow of the motion shown in Fig 1 agree pretty closely with those that can be computed from Rayleigh's formula, the main difference being that the distance from the wall to the surface at which the direction of flow reverses is found experimentally to be 0 33 times the radius, while according to Rayleigh's calculation the figure comes out to be 0 293

The other new phenomenon is the motion of the air caused by the presence of an obstacle, and hence by a particle of dust, the inertia of which is sufficient for there to be a large motion of the surrounding air relative to it When certain critical conditions, suggested by application of the principle of dynamical similarity, are satisfied, a vortex system of the type represented in Fig 2 is formed round a spherical obstacle, a similar system, modified in the general way to be expected, has been detected round a cylindrical obstacle This is believed to be the first example of a vortex system generated by a vibrating fluid

FIG 3 —Method of formation of dust ridges by means of vortices

Such vortices are the cause of the ridge systems which form in an excited Kundt's tube, the general method of formation of the ridges being illustrated in Fig 3, where two cylindrical obstacles, lying on the floor of a flat tube, are shown in equilibrium It has been found that a combination of the general circulation and of the vortex motion caused by particles can account for practically all the phenomena which take place in a dust tube

Determination of the Molecular Weight of Insulin

AT the suggestion of Dr H Jensen, of the Johns Hopkins University, Baltimore, an ultracentrifugal investigation of insulin has been carried out in my laboratory by Mr B Sjögren A quantity of 0·25 gm crystalline insulin was kindly put at my disposal by Dr Jensen, and this small sample proved sufficient

for a fairly complete study of the molecular weight and pH stability region of insulin

Twelve determinations of the sedimentation of insulin in centrifugal fields 100,000 times the force of gravity at 20° C over a pH-range of 3 5 12 3 showed that insulin is stable from about pH 4 5 to about 7 0 The sedimentation constant has a value of $3\ 47 \times 10^{-13}$, which is very close to the value $3\ 54 \times 10^{-13}$ previously obtained for egg albumin, and that for Bence Jones protein, namely, $3\ 55 \times 10^{-13}$ When the stability range is exceeded, dissociation into low molecular products takes place This dissociation is reversible if the substance has not been brought too far into the acid or alkaline region and has not been kept there too long

Three determinations of the sedimentation equilibrium of insulin at a pH of 6 7-6 8 gave as a mean value for the molecular weight 35,100, which within the limits of experimental error is the same as that for egg albumin, 34,500, and for Bence Jones protein, 35,000 For the partial specific volume the value 0 749 was obtained This constant also is identical with that of egg albumin and Bence Jones protein A calculation of the molar frictional constant from the above data gives the result that the insulin molecule is spherical, which is also the case with the molecule of egg albumin and Bence Jones protein

The sedimentation equilibrium determinations show that crystalline insulin is homogeneous with regard to molecular weight, that is, the molecules in the sample studied were all of the same weight

The above results seem to demonstrate that insulin is a well defined protein belonging to the same class as egg albumin and Bence Jones protein (compare NATURE, June 8, 1929, p 871) As pointed out by Dr Jensen in a letter to me, this fact makes it very improbable that the sythesis of insulin will ever become possible

Viscosity of Electrolytes

THE investigations of Jones and Dole [1] suggested to me the problem of studying the viscosity of strong electrolytes from the viewpoint of the theory of Debye [2] It is well known that Debye's theory assumes that each ion is surrounded by an 'ionic atmosphere' the total charge of which is equal and opposite to the total charge of the central ion

The ionic atmosphere has a definite thickness and in addition requires a certain time for its formation, which is called the time of relaxation Both the thickness and the time of relaxation are dependent in a definite manner on the concentration, the valence of the ion, the temperature, and the dielectric constant of the solvent Furthermore, the time of relaxation is a function of the mobility of the ions

The properties of the ionic atmosphere are of great significance in a consideration of the reversible thermodynamic and irreversible conductivity processes of strong electrolytes [3] They also make it possible to construct a picture of the irreversible mechanism that is involved in the viscosity phenomena exhibited by strong electrolytes To illustrate this, we might consider the following case Imagine a plane perpendicular to the axis along which the velocity of the ions is changing If we take into consideration the successive layers above the plane, it can be shown that as a result of the electric lines of force coming from the added electric charge, a force is built up on the central ion parallel to the x axis (see Fig 1)

The total shearing force which is produced over an area of one square centimetre lying perpendicular to the velocity gradient can be readily calculated In making this calculation, the negative ions with their deformed ionic atmospheres must also be taken into consideration In this case the distribution of the electric charge is complementary to the corresponding distribution of the charges in Fig 1 This force is proportional to the velocity gradient The proportionality factor is obtained by adding to the viscosity of the original solvent the effect due to the Coulomb forces existing between the ions

If we call the viscosity of the electrolyte η_γ in normal concentration γ (in mols per litre), η_0 the viscosity of the pure solvent, then I can derive the

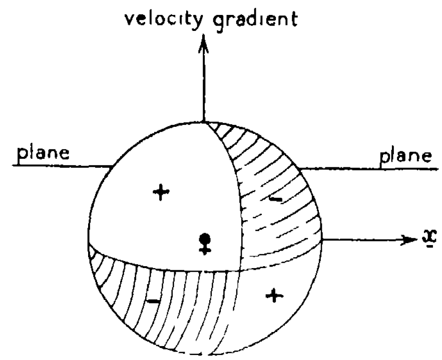

FIG 1

following relation theoretically which holds (or is applicable) in the case of dilute solutions

$$\eta_\gamma = \eta_0(1 + A\sqrt{\gamma})$$

In this expression A is dependent in a definite manner on the valence of the ion, its mobility, the absolute temperature, the dielectric constant, and the viscosity of the pure solvent η_0 For potassium chloride at 18° we obtain $A = 0\ 0046$ with water as solvent Recently Joy and Wolfenden [4] have verified this predicted value experimentally

In this connexion it may be interesting to note that I have recently calculated the general expression for the viscosity of any simple strong electrolyte and that I have also derived the general limiting law (*Grenzgesetz*) for viscosity phenomena The expression is the same as that indicated in the formula above, except that the coefficient A is in this case dependent in addition, in a much more complicated manner, on the mobilities and valences of both ions I do not propose to give the expression in detail here, for it is to be published shortly [5]

It would be very interesting to compare the theoretical results with systematic experimental studies, which will have to be carried out in the future A systematic investigation of the viscosity of weak electrolytes as a function of concentration, etc, would also be very interesting I believe that in this case the dependence of the viscosity on the concentration does not follow the square root law, but presumably is linear These linear terms are also important for the more concentrated solutions of strong electrolytes Perhaps it would be possible to develop further the exact differential equations pertaining to the problem so that this field may be explored In doing this, it will be necessary to take into consideration the relaxation effect of the dipole molecules of the solvent on the viscosity of the solution This has recently been calculated by Finkelstein, [6] according to whom this effect is proportional to the concentration

Although I am at present not fully convinced as to the validity of the quantitative values calculated by Finkelstein,[6] it nevertheless appears that some interesting explanations of the structure of electrolytic solutions are to be expected by comparison with experimental results

Electromotive Force of Dielectrics

I FOUND some time ago[1] that glasses in aqueous solutions show the electromotive force of a solid electrolyte the ion in the solid glass determines the potential difference against the solution Moreover, it could be shown that cations from the solution were exchanged against the cations in the glass the glass behaves then like a mixed electrode, but in a certain range of concentration practically like an electrode reversible to the ions taken up from the solution Glasses which show definitely the behaviour of a solid electrolyte (sodium electrode) also show always exchange electrodes particularly the silver and hydrogen electrode Certain soft glasses show only the hydrogen electrode except in alkaline solution

It was of interest to investigate whether other dielectrics would also show the same behaviour With J Hatner and lately with J E Ferguson, I investigated the electromotive behaviour of fused silica In this case also we found the existence of the sodium, silver, and hydrogen electrode

In the case of quartz, as in the case of glasses, the electromotive behaviour corresponds to the observations made when a current passes the solid

J E Ferguson and I[2] have investigated during the last year the electromotive behaviour of thin paraffin films We found also in this case the existence of sodium, potassium, hydrogen, and silver electrodes, and also (with some slight deviations, however) the existence of a calcium electrode, which we failed to find in any of the glasses investigated

These phenomena can be understood[3] if we make the following assumption The number of places available for cations in the dielectric is limited and constant $(=a)$ Only one kind of ion, cations, are taken up by the solid, and only these ions can migrate in the solid In the state of equilibrium the difference of potential, solid-solution, is the same for all kinds of ions present Neglecting the number of ions given off by the solid as compared with the concentration, c, in the solution, and treating the solid phase in first approximation like a dilute solution, the following formula is obtained for two kinds of ions present

$$E - \frac{RT}{F} ln \frac{\frac{K_1}{u_1} u_2 a}{c_1 + \frac{K_1 u_2}{K_2 u_1} c_2}$$

and ΔE the potential difference in the 'concentration cell' which alone is being measured

$$\Delta E = \frac{RT}{F} ln \frac{c_1' + Ac_2'}{c_1 + Ac_2} \left(A = \frac{K_1 u_2}{K_2 u_1} \right)$$

In this formula c_i are the concentrations in the solution, u_i are the mobilities in the solid phase, K_i are the integration constants in the expression for the thermodynamic potential of the ions present in the solid phase (solution tension)

In this formula all the terms can be measured directly, since also A is given by a single experiment For permutites and certain glasses, more complicated formulæ have to be used, since the ions in the solid phase cannot be treated as independent of one another, and since the amount of ions exchanged is comparable with the concentration of the ions in the solution

Protein Structure and Denaturation

ASTBURY and Woods' fundamental work upon the micellar structure of the protein of wool fibres,[1] and the hypothesis they put forward as an explanation of the changes observed in the X ray pattern when such fibres are stretched, would seem to be full of significance for protein chemistry in general

Within the last ten years, different lines of evidence have been converging upon the view that some regularity, as regards pattern and molecular size, underlies the disordered confusion of data we possess relating to the proteins of the animal and vegetable kingdoms The two most striking demonstrations in recent years of such uniformity are afforded by Svedberg's brilliant application of the ultracentrifuge to determine the particle mass of soluble proteins,[2] classes of 'molecular weight' 1, 2, 3, and 6 times the common factor 34,500 being distinguished, and Gorter and Grendel's demonstration[3] that under appropriate conditions soluble proteins exhibit the phenomenon of surface spreading on liquids, and that all occupy the same surface area irrespective of particle mass (1, 2, 3, or 6 times 34,500) Using Svedberg's common factor 34,500 for the basis of their calculations, the Dutch workers obtain a value for the radius of the unit particle (22 5 A) identical with that determined by Svedberg experimentally

The most significant feature of Gorter and Grendel's work, however, is that their results imply a loosening, brought about by the surface forces, of the cohesive attraction holding the units of the aggregated proteins together Astbury and Woods' investigations reveal a somewhat similar, although internal, deformation of the keratin structure of the wool fibre, brought about by purely physical means Our conceptions of the chemical reactivity of protein structures clearly need revision in an attitude of greater attention to modern valence conceptions

One more point cannot be too clearly emphasised which is common to the essential findings of Svedberg, Astbury and Woods, and Gorter and Grendel the changes observed by these workers are strictly *reversible*

In conclusion, I should like to touch upon the problem of protein denaturation, and to inquire whether it is not in the direction of such work as that of Astbury and Woods that we have to look for a solution of this problem? Denaturation of proteins, which can be brought about by mechanical as well as by chemical forces, is characterised by a loss of solubility at the isoelectric point It was always thought to be an irreversible change, but Anson and Mirsky[4] have recently demonstrated its reversible nature in

the case of globin Some internal alteration takes place during denaturation, as evidenced by the change in reactivity of the sulphur groups,[5] but neither acid or base binding capacity [6] nor osmotic pressure [7] are affected—that is to say, there is no scission Clearly, loss of isoelectric solubility must be due to change in some internal tautomeric configuration

It is difficult to avoid the suggestion that a change, similar to that postulated by Astbury and Woods in explanation of the behaviour of the stretched and unstretched wool fibre, may in reality be the essential happening attending denaturation The -CO-NH- group possesses strong polarity, but, by the rearrangement of peptide linkages into what are virtually closed ring systems, affinity for water would be enormously diminished At present there exists no satisfactory hypothesis offering an explanation of denaturation Such a scheme as the above may reasonably be entertained until further evidence can be brought forward of a chemical or physico chemical nature which will throw more light upon the problem Considering the remarkable and wholly unexpected results, mentioned above, of Gorter and Grendel, working upon protein surface films, it would seem that quantitative data bearing upon denaturation is likely to be obtained most readily by studies having a similar approach The forces at play within the liquid and at the interface possess no mean magnitude They are, however, susceptible of more precise control and exact manipulation than those involved in, let us say, heat coagulation or the application of vigorous chemical reagents From a study of the surface phenomena exhibited by proteins under varying conditions, coupled possibly with an application of the X ray method to films of such proteins as can be made to give readily detectable diffraction photographs,[8] a solution not only of the denaturation process but also of the structure of native proteins may, in the future, be obtained

Stellar Structure

THE current argument against Helmholtz's contraction hypothesis concerning the origin of the sun's heat may be summarised as follows The gravitational potential at a point within the sun is of the order of magnitude of its value at the surface, 2×10^{15} c g s units Thus contraction may have supplied energy 2×10^{15} ergs per gram of the sun's mass The sun now radiates 1 9 ergs per second for each gram of its mass Further, the earth's crust has been solid for at least $1\ 6 \times 10^{9}$ years, during which time the sun may have radiated 9×10^{16} ergs for each gram of its mass Hence "it appears that the Helmholtz contraction-hypothesis cannot account for more than about two per cent of the energy which has been radiated by the sun during the earth's life" (Jeans, "Astronomy and Cosmogony", p 106) Further, there is astronomical evidence that the whole life of the sun has been at least of the order of 10^{13} years

It seems to have been overlooked that modern theories concerning the internal temperature and density distribution in the stars very much weaken, if they do not quite destroy the above argument If, following Milne,[1] we suppose that the mass of the star is much concentrated towards the centre, the first part of the above argument loses its force Fifty times as much energy can be accounted for The longer time period of 10^{13} years may be due in part to the sun's not having in the past radiated so much as it does at present

If the opacity of the stellar material varies as $T^{\frac{1}{2}}f(\rho/T^{3})$, where ρ is the density and T the temperature (the only theoretical formula in the field is of this form), it is possible that gaseous spheres of such material should contract to homologous density distributions and obey Lane's law Such spheres can exist possessing any mass, radius, and luminosity within certain limits, though, as I have shown,[2] this homologous contraction is a very special case The mass, radius, and luminosity, however, determine the rate of contraction The whole time required for the star to contract to its present size is $2(3R - C_v)MT/L$, where L and M are its present luminosity and mass, R and C_v the gas constant and specific heat of the material, and T the mean internal temperature

For the sun, taking mean temperature 10^{9} degrees, and $(3R - C_v)$ to be $2\ 5 \times 10^{8}$ ergs per gram per degree, this gives a past life of 8×10^{9} years This would be increased proportionately if, following Milne, we estimated the mean temperature of the sun higher The total energy radiated in the above life works out at $2\ 4 \times 10^{17}$ ergs per gram and the corresponding mean gravitational potential is $4\ 8 \times 10^{17}$ c g s units, not at all impossible if there is much concentration of mass towards the centre In its early stages, however, the contraction would have been much slower, since, for smaller T, R would have been larger, and the opacity also would have been larger than that given by the above formula Indeed, opacity varying as $T^{-1}f(\rho/T^{3})$ gives an infinite time scale

Helmholtz's hypothesis appears, therefore, by no means to be untenable

Replacing the Telephone by a Loud Speaker in Conductivity Measurements

IT seems improbable that nobody should have ever tried replacing the telephone by a loud speaker in conductivity measurements, but I have never heard of it, nor read anything about its possibility and advantages, I will, therefore, describe it very briefly, as I feel convinced that it represents a real improvement over the customary procedure

It consists simply in a two stage amplifier, with a factor of amplification of about 500, connected to a Kohlrausch bridge for measuring electrolytic conductivity, instead of the usual telephone, which is replaced by loud speaker If, instead of a buzzer, a shielded oscillator is used, and if all the leads are lead covered and properly earthed, the apparatus can be adjusted to give a musical note of variable intensity which permits the determination of the minimum sound much more easily, agreeably, and even a little more accurately than with the telephone I have found it a great improvement, and I hope this letter will encourage those interested in resistance measurements to try this scheme, which possibly they have not used before simply because they were doubtful about its advantages

The Nature of the Virus Principle in Mosaic Disease

DURING the course of investigations designed to determine the nature of the infective principle present in the virus of tomato mosaic, a bacterial growth showing various forms was isolated Stained smears prepared from this showed so many bacteria in a state of breakdown that the phenomenon seemed worth examining further

The original isolations were prepared as follows Pieces of tomato stem taken from plants showing symptoms of mosaic disease and 'stripe' disease, were sterilised on the outside with calcium hypochlorite, and inserted into tubes of potato agar No growth resulted for ten weeks, but in the twelfth week three tubes showed a grey-brown bacterial growth on the agar round the piece of tomato tissue

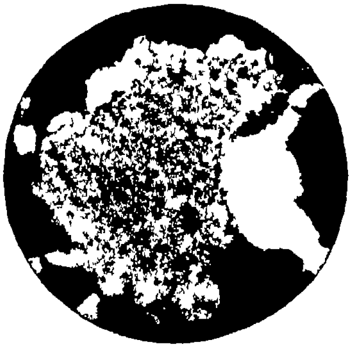

FIG 1

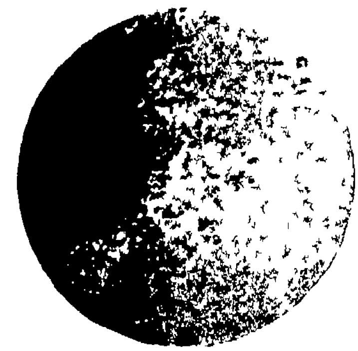

FIG 2

FIG 3

Stained smears showed small clear areas (Fig 1) at a magnification of 150 (In the reproduction, all the illustrations have been reduced to two-thirds of their original size.) When examined at a magnification of 1250 these areas appeared as in Fig. 2 The bacterial cells had been destroyed, leaving a granular deposit with deeply staining fragments strongly resembling minute organisms At other portions of the smears (Fig 3), certain cells were seen to be much swollen and speckled with minute darkly staining granules Cultures of the original growth were emulsified with water and filtered through a sterile Chamberland $L3$ filter When added to a broth culture of the original growth which had been freed so far as possible from 'phage', some slight clearing and diminution of the number of bacteria resulted

In view of the conditions under which the original isolations were obtained, it seemed possible that the bacteriophage principle present in the cultures might be the active virus of mosaic disease present in the tomato tissue from which the isolations were prepared

Consequently, a quantity of virus was extracted from a tomato plant originally inoculated with the virus of *Aucuba* mosaic disease, but which, since inoculation, had also developed symptoms of 'stripe' disease Portions of the virus which had passed through $L3$, $L5$, and $L7$ filters under aseptic conditions were tubed separately These were added in 1 c c lots to turbid potato broth cultures of the original growth which had been freed so far as possible from 'phage' In 24 hours, the tubes receiving filtrates from the $L3$ and $L5$ filters showed slight clearing, and in 48 hours, there was definite clearing of these tubes, and in some cases very slight clearing and browning where the filtrate from an $L7$ filter had been added Microscopic examination of drops from the cultures showed an appreciable diminution of bacterial numbers accompanied by apparent fragmentation when the filtrates from $L3$ and $L5$ filters were added Poured plates confirmed this observation

Potato broth tubes to which $L3$ filtrate of healthy tomato juice was added remained turbid, and neither decrease in the number of bacteria present nor change of form have been observed The action of the virus seems limited to certain organisms, for when added to mixed broth cultures prepared from soil and horse manure, no obvious clearing or browning resulted

In view of these results, which have been repeatedly obtained, it is suggested that the principle causing mosaic disease of the tomato is of the bacteriophage type, which, in the first place, enters the plant with the organism it parasitises in Nature and, becoming adapted to life within the tissues of the tomato plant, causes the symptoms now associated with mosaic disease

If this view be correct, its implications in the study of virus diseases are considerable

Cheshunt, Herts, Mar 5

Hardening of *Moti*, a Japanese Rice Food-stuff.

IN the course of my researches on the mechanism of the setting and hardening of cement, and on account of the similarity of the problems involved, I have investigated also the problem of the hardening of *moti*, a Japanese rice food-stuff Glutinous rice, previously steamed with special apparatus, is made into *moti* by pounding In the air, it hardens into a stone-like mass The results I have obtained so far are as follows

(1) The hardening phenomenon occurs in two ways: (*a*) It may be due to desiccation, that is, the water in the *moti* goes off into the air, the result being the formation of a stone like mass, or (*b*) it may be due to internal changes For example, when freshly prepared soft *moti* is preserved under paraffin, although desiccation is thus prevented, the *moti* hardens, but to a somewhat soft mass This mass hardens further on exposure to the air, cracking and forming a stone like mass

(2) By differential thermal analysis in a specially designed vessel, during both cooling and heating, *moti* shows at 63 5° C a transition point This change is reversible The transition point does not appear with freshly prepared *moti*, but it appears with *moti* which has been cooled once in a hermetically sealed vessel

(3) J R Katz (*Zeit physik Chem*, A, 150, 37, 1930, etc) suggested a transition point at about 60° C in the staling process of bread, and thinks the existence of this point is the cause of bread becoming stale So far as *moti* is concerned, this does not

hold good, although it has some relation to the cause of the hardening of *moti* referred to in (1) *Moti*, when once hardened, can begin to soften at a temperature somewhat below the transition point, and the water of *moti* is connected with its hardness These facts show that the constitution below and above the transition point is not the only factor in the determination of hardness

(4) My views (*J Phys Chem*, **31**, 933, 1927 *Zement*, **19**, 842, 1930) on the mechanism of the setting and hardening of cement are to a great extent applicable also to the hardening process of *moti* In brief, the hardening is due to the decrease of free water in the system In the case (1*a*) above, free water in *moti* escapes to the exterior In the case (1*b*), free water which exists at higher temperatures loses its freedom in cooling, becoming water of crystallisation, adsorbed water, etc It may be that the transition point 63 5° C is connected with the water of crystallisation As to the water of crystallisation in starch, the opinion of St v Naray Szabó (*Zeit physik Chem*, A, **151**, 420, 1930) is suggestive

Details of this work will appear in the *Scientific Papers* of this Institute

Geo-electrical Prospecting.

IN my article published in NATURE of Jan 3 of this year, entitled "Geo electrical Prospecting by A C Bridge Methods", I stressed a disadvantage of the well-known A C equipotential line method of prospecting, which is sometimes so serious as to preclude the use of the method altogether The difficulty arises from the fact that large out of phase components occur in the neighbourhood of the more highly conducting ore-bodies and that in such circumstances it is impossible to locate equipotential points with any degree of accuracy In extreme cases there are no distinguishable minima from which the general trend of the current distribution may be determined

I am writing to direct attention to a means of overcoming this difficulty which was recently suggested to me by D C Gall, who at the time was visiting one of my field parties He proposed that a small search coil should be placed in series with the detecting circuit, which usually consists of a pair of pointed rods connected by 50 feet or so of wire to an amplifier and headphone Since the e m f induced in the coil will be in quadrature with the current, whereas that in the ground is approximately in phase with the current, it was to be expected that by suitably orientating the search coil it would be possible to balance the out-of-phase component and so locate the *in phase* equipotential points with precision

Mr Gall's suggestion has now been tried out and has proved most satisfactory, and there can be no doubt that it constitutes an improvement in the equipotential line method which will prove of great practical value In the tests recently carried out, the coil was permanently attached to the amplifier box on the back of the operator The latter, by slightly adjusting the position of his body, can quickly bring the coil into such a position that the equipotential points may be accurately located on the ground, complete silence being observed in the telephones

17	24	7	4	13

In NATURE of Oct 17, 1925, p 573, I gave the above, but I was not then able to give the number of squares of *B* and *C* I can now complete this *A* has a 'Heart' magic in its 3 rows, 3 columns, and 2 diagonals, and with its 21 positions inside a square of 5th order has 649,168 squares *B* has a 'Heart' with only its 3 rows, 3 columns magic, and with its 21 positions of all proportions from 52/13–26/39 has 720,388 squares *C* has a 'Heart' without the number 13, and in its 18 positions has 3656 squares

Including all types of squares thus far, I have brought the grand total of magic squares of 5th order, whose 5 rows, 5 columns, and 2 diagonals are magic, to 1,623,768 One type only has one solitary square, but this type can be transformed by inversion into three other types, with their complementary squares of the proportion 52/13, each having a solitary square I give it as unique

Climatic Control in the Reproductive Cycle

IN my letter in NATURE of Feb. 7, p 200, entitled "Embryology and Evolution", I referred to a correlation between magnetic solar radiation and the reproduction of fur-bearing animals Statements to the effect that such a correlation has been proved to exist are frequent, and are also found in certain text-books, but there seems to be considerable doubt as to their validity

I have, therefore, sought to obtain reliable evidence on this subject, and I am indebted to the Governors and Committee of the Hudson's Bay Company, and to Mr Charles Elton, of Oxford, for information which is of value in showing that such a correlation was originally suggested by Mr Elton in 1924 as an *hypothesis* only, and that it has erroneously been elevated gradually by others to the rank of fact

I am informed by the Hudson's Bay Company that its trading operations are not based on the indications of sunspot activity nor on those of other meteorological conditions, while Mr Elton's view is that though sunspot influence *has to* be ruled out definitely, there is, nevertheless, some proof of climatic control in the reproduction cycle of fur bearers

The phenomenon of photoperiodicity in plants might well be substituted in my original argument as an example of an external control in the activities of the living cell

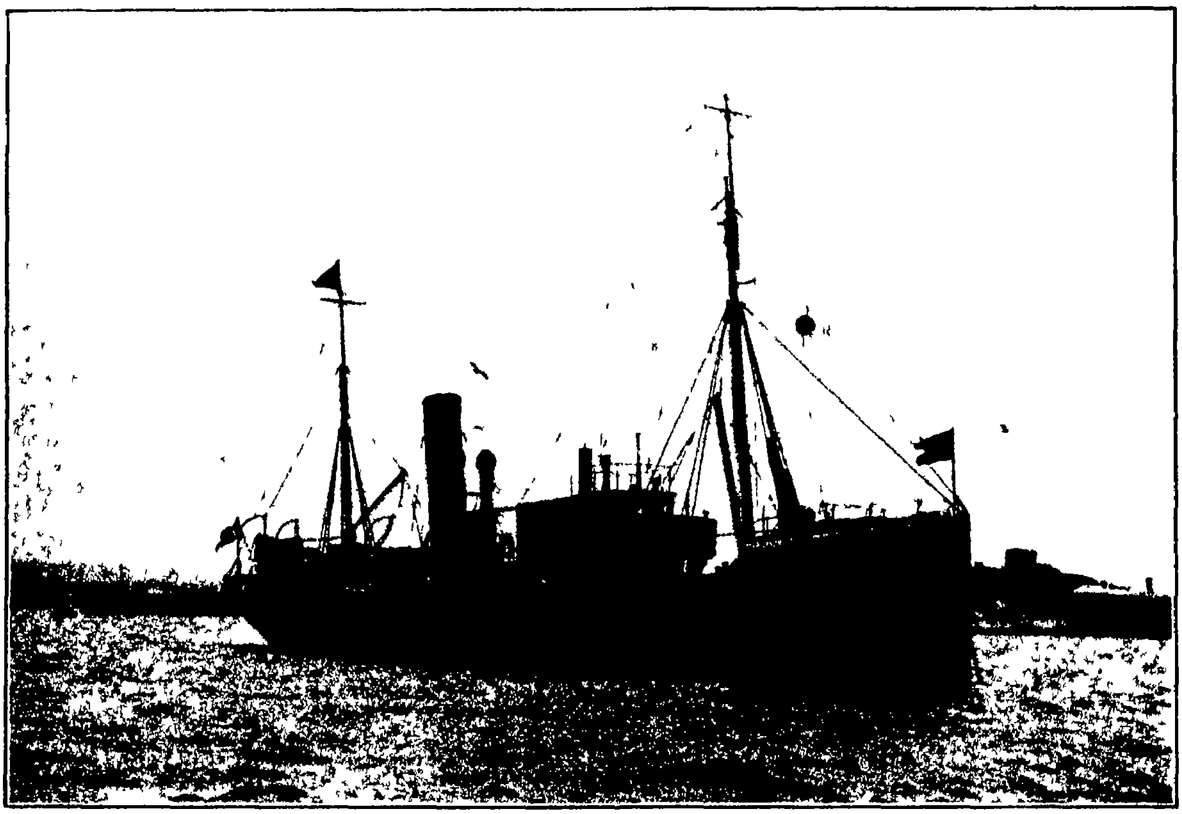
Oceanographical Expedition of the *Dana*, 1928–1930

By Prof Johannes Schmidt, Ph D, D Sc,
Carlsberg Laboratory, Copenhagen, Leader of the Expedition

In Nature of Dec 29, 1928, Prof D'Arcy W Thompson gave an outline of the plans and scope of this expedition on board the Royal Danish Research Ship *Dana* This vessel, with its experienced master, Captain G Hansen, and staffed by officers of the Royal Navy, was placed at the disposal of the expedition by the Danish Government The cost of the expedition however, was defrayed by the Carlsberg Foundation, the largest scientific fund in Denmark, hence the official title "The Carlsberg Foundation's Oceanographical Expedition round the World 1928–30 under the Leadership of Professor Johannes Schmidt"



Photo] [The Times

Fig 1 —Royal Danish Research Ship *Dana* (360 tons) at anchor in Plymouth Roads June 21, 1930, on her return from the circumnavigation expedition

Prof D'Arcy Thompson has already noted in detail one of the main tasks of the expedition, namely, an investigation of the life-history of the Indo-Pacific fresh water eels (*Anguilla*), in similar fashion to the work I had already carried out in the case of the North Atlantic fresh water eels What I propose to do here is to give a brief account of the main points in the working methods and plans of the expedition, and then give two illustrations of the results, one drawn from the biological side, the other from the hydrographic side, the latter has been prepared by my colleague, Mr Helge Thomsen

Admiral H R H Prince Valdemar of Denmark was patron of the expedition, and it was controlled by a committee, the presidents of which were the late Prof C H Ostenfeld and Prof A B Drachmann, president of the Carlsberg Foundation, G C Amdrup, Vice-Admiral of the Royal Danish Navy, was vice-president of the committee

It was my good fortune to have among the scientific workers several colleagues from my earlier expeditions, the zoologists Dr P Jespersen, Dr Å V Tåning, and Mr A F Bruun, the physicists Dr J N Nielsen and Mr Helge Thomsen, and the botanist Prof Ove Paulsen, the botanist Mr E Nielsen also took part in the expedition Further, two Danish zoologists, Dr Th Mortensen and Dr R Spärck, spent some time on board engaged in bottom work, the former at St Helena and the Canaries, the latter in the Mediterranean

The expedition occupied two years The *Dana* left Copenhagen on June 14, 1928, and after circling the globe in a westerly direction, returned home on June 30, 1930 The total number of stations amounted to 661, and the distance covered was 65,000 miles, with a coal consumption of 3358 tons It should be mentioned that the

Dana, through her short-wave radio station, was in direct communication with the Copenhagen station during the whole expedition, even at the to those of the *Challenger* expedition, in which the pelagic collections played a more subordinate part

The most characteristic features of the working

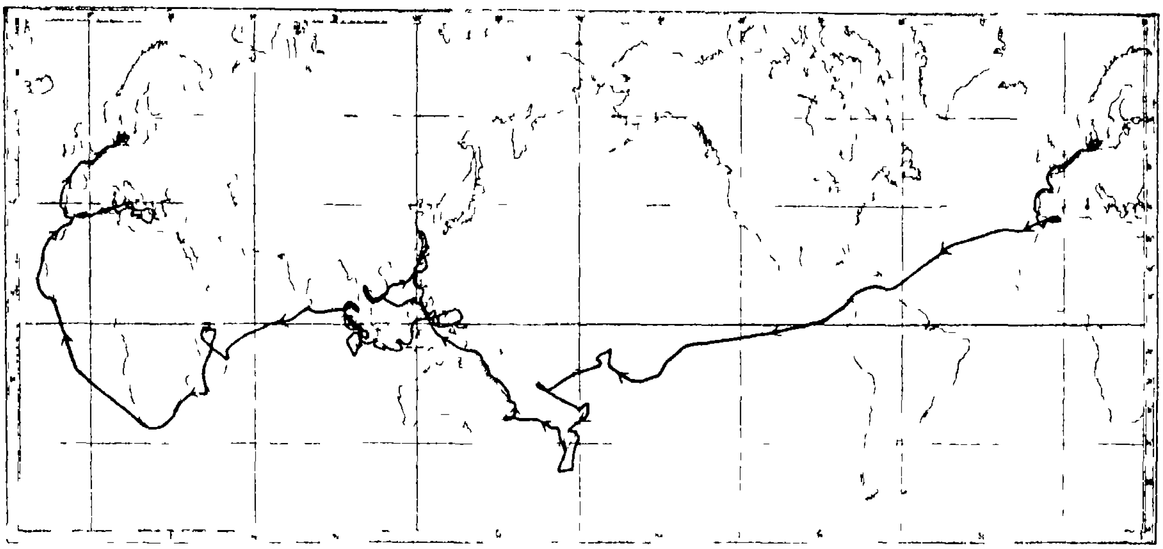


FIG 2 —Route of the *Dana* round the world June 14 1928–June 30 1930

antipodal region near New Zealand the communication was perfect

The route mapped with regard to the eel investigations was carried out almost completely according to plan, but owing to the limited coal capacity of our small vessel, we did not succeed in visiting all the regions in the Pacific and Indian Oceans that had been included in the scheme The chart (Fig 2) shows the course of the *Dana* round the world It ran in the main parallel with the equator, except in the western Pacific and on the last lap, where it turned vertical to the equator from the Cape of Good Hope homewards

The object of the expedition was not to bring home collections of zoological rareties The main general task was to study the distribution of the commonest oceanic species and genera in the three great oceans, and—having regard for the physical and chemical conditions under which they live—to seek some understanding of the factors concerned in this actual distribution and to make some contribution to their life-histories

Whilst the expedition of the *Dana's* great predecessor, the *Challenger*, was chiefly concerned with the investigation of the bottom and its fauna, our expedition was in special degree a pelagic expedition We investigated especially the upper and middle water layers and their inhabitants, and as we had the best pelagic fishing apparatus of the present time at our disposal, I venture to hope that our results will form, to a not inconsiderable extent, a supplement methods and plans of the *Dana* expedition may be summarised in three groups

1 With the aid of the most efficient apparatus, to obtain a very large material, rich in individuals, of the pelagic life in the different depths of the various oceans

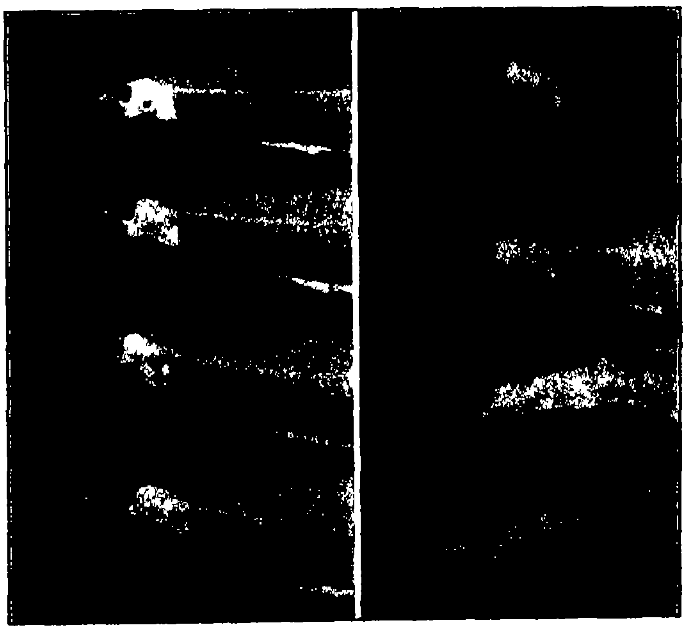

FIG 3 —Metamorphosis of *Nessorhamphus ingolfianus*, Johs Schmidt Specimens from the Sargasso Sea, showing transformation from the larval to the eel stage Photo A F Bruun

d „ „ 82 mm
e Metamorphosis stage 84 mm
f „ „ 78 5 mm
g „ „ 83 mm
h „ „ 88 mm

2 With the aid of simultaneous, methodical

investigations on the physical and chemical composition of the different water layers, to obtain data which would permit us to conclude under what environmental conditions each single one of the millions of pelagic organisms, taken in our nets, may live

3 By means of the large pelagic material, which in numerical richness of the single species presumably surpasses that of earlier expeditions round the world, to subject a number of important oceanic species or genera to a finer analysis, with reference to classification, than has previously been possible with the frequently somewhat scanty material available from the distant waters To supplement the third point, I may add that the investigations of recent years, *inter alia* those especially of the fresh water eels, have shown that the treatment of the life history of a form (in part also of its distribution) must descend to the lowest systematic units But these units cannot be reached, as a rule, unless one has a large material of individuals, on which one can use biometric methods similar to those applied by Heincke and others to various northern food fishes, and which I have myself used for a number of years in the series of " Racial Investigations " published by the Carlsberg Laboratory since 1917

I nourish, therefore, the hope that our large and rich material from the three oceans, dealt with in this manner and from this point of view, may contribute new and important information regarding the species and genera of the pelagic fauna, their distribution in the oceans, their dependence on environmental conditions, and their life histories I refer here specially to the fishes which seem in marked degree suitable to biometric treatment, not least because the numerous larvæ can often be included in the investigation—several of the principal characters for the finer analysis, such as number of fin rays and especially vertebræ, being already fixed in the larval stage In addition, my assistants, several of whom took part in the expedition, are well acquainted with these investigations, each in his own group—I may mention here Dr Å V Tåning, whose work on the specifically and individually rich group of Scopelids has already won general recognition

The expedition's field of operations embraced not only the three oceans, but also many of the principal enclosed seas , Mediterranean, Caribbean, Banda, Celebes, Sulu and Mindanao, and the China Seas The following table summarises the number of the principal pelagic and hydrographical operations, etc , in the three oceans

	South Pacific	North Pacific	Indian Ocean	Atlantic
Horizontal hauls with large pelagic nets	606	377	1046	1034
Vertical hauls with silk nets	162	97	74	161
Deep sea water samples	1110	765	917	1383
Echo soundings	2025	896	2215	3064

It will naturally take some time before the large amount of material can be worked out fully, but a few examples of the results of the expedition may already be given

(*To be continued*)

Centenary of William Symington

By Eng Capt EDGAR C SMITH, O B E , R N

THE invention of the steam boat, or rather the application of the steam engine to the propulsion of vessels, the successful solution of which involved many problems, will always remain one of the great landmarks of human progress On no other single project of the same nature, perhaps, was time and thought, energy and wealth, expended so lavishly, and the recognition of the labours of its inventors is, therefore, a moral obligation Many of the projectors of steam navigation are known to us only by their patents or pamphlets, some are remembered for their ingenious suggestions and inventions, and a few by their persistent efforts to achieve what the majority of their fellows thought impracticable ' Crazy Rumsey " and Fulton's Folly " are but two of the epithets which remind us of the scepticism the pioneers had to face But neither derision nor opposition, failure nor disappointment, loss of health nor wealth, could stay the hand of progress There was always someone to step into the ranks to take the place of the fallen until the final goal was reached

" Generally what is usually called an invention ", said the late Sir Charles Parsons, " is the work of many individuals - each one adding something to the work of his predecessors " This was true only to a limited extent in the case of the steam boat, for the experiments of the Marquis de Jouffroy in France, of Fitch, Rumsey, Stevens, and Fulton in the United States, and of Miller, Symington, Stanhope, and Bell in Great Britain, were largely independent of each other Steam navigation as a regular means of transport is usually associated with the *Clermont* of Fulton and the *Comet* of Bell, built respectively in 1807 and 1812, but, as a matter of fact, the problem had already been completely solved in 1802 by Symington when he engined the *Charlotte Dundas*, and it was a cruel stroke of fate which robbed him of the fame which should have made him known as the ' father of steam navigation ' The machinery he placed in the *Charlotte Dundas* was not surpassed in simplicity and suitability for fifty years , it was far superior to that used by any of his predecessors, or even that supplied by the famous firm of Boulton and Watt for Fulton's *Clermont* If, therefore, he is denied the title of the ' father of steam navigation ', no one can withhold from him the name of the ' father of marine engineering '

Symington, the centenary of whose death occurs on Mar 22, was born in the mining village of Lead-

Supplement to NATURE

No 3203 MARCH 21, 1931

The End of the World from the Standpoint of Mathematical Physics.*

By Sir ARTHUR S EDDINGTON, F R S

THE world—or space-time—is a four dimensional continuum, and consequently offers a choice of a great many directions in which we might start off to look for an end, and it is by no means easy to describe "from the standpoint of mathematical physics" the direction in which I intend to go I have therefore to examine at some length the preliminary question, Which end ?

SPHERICAL SPACE

We no longer look for an end to the world in its space dimensions We have reason to believe that so far as its space dimensions are concerned the world is of spherical type If we proceed in any direction in space we do not come to an end of space, nor do we continue on to infinity, but, after travelling a certain distance (not inconceivably great), we find ourselves back at our starting point, having 'gone round the world' A continuum with this property is said to be finite but unbounded The surface of a sphere is an example of a finite but unbounded two dimensional continuum, our actual three dimensional space is believed to have the same kind of connectivity, but naturally the extra dimension makes it more difficult to picture If we attempt to picture spherical space, we have to keep in mind that it is the *surface* of the sphere that is the analogue of our three-dimensional space, the inside and the outside of the sphere are fictitious elements in the picture which have no analogue in the actual world

We have recently learnt, mainly through the work of Prof Lemaître, that this spherical space is expanding rather rapidly In fact, if we wish to travel round the world and get back to our starting point, we shall have to move faster than light, because, whilst we are loitering on the way, the track ahead of us is lengthening It is like trying to run a race in which the finishing tape is moving ahead faster than the runners We can picture the stars and galaxies as embedded in the surface of a rubber balloon which is being steadily inflated, so that, apart from their individual motions and the effects of their ordinary gravitational attraction on one another, celestial objects are becoming farther and farther apart simply by the inflation It is probable that the spiral nebulæ are so distant that they are very little affected by mutual gravitation and exhibit the inflation effect in its pure form It has been known for some years that they are scattering apart rather rapidly, and we accept their measured rate of recession as a determination of the rate of expansion of the world

From the astronomical data it appears that the original radius of space was 1200 million light years Remembering that distances of celestial objects up to several million light years have actually been measured, that does not seem overwhelmingly great At that radius the mutual attraction of the matter in the world was just sufficient to hold it together and check the tendency to expand But this equilibrium was unstable An expansion began, slow at first, but the more widely the matter was scattered the less able was the mutual gravitation to check the expansion We do not know the radius of space to-day, but I should estimate that it is not less than ten times the original radius

At present our numerical results depend on astronomical observations of the speed of scattering apart of the spiral nebulæ But I believe that theory is well on the way to obtaining the same results independently of astronomical observation. Out of the recession of the spiral nebulæ we can determine not only the original radius of the universe but also the total mass of the universe,

* Presidential address to the Mathematical Association, delivered on Jan. 5.

and hence the total number of protons in the world I find this number to be either 7×10^{78} or 14×10^{78} * I believe that this number is very closely connected with the ratio of the electrostatic and the gravitational units of force, and, apart from a numerical coefficient, is equal to the square of the ratio If F is the ratio of the electrical attraction between a proton and electron to their gravitational attraction, we find $F^2 = 5.3 \times 10^{78}$ There are theoretical reasons for believing that the total number of particles in the world is aF^2, where a is a simple geometrical factor (perhaps involving π) It ought to be possible before long to find a theoretical value of a, and so make a complete connexion between the observed rate of expansion of the universe and the ratio of electrical and gravitational forces

Signposts for Time

I must not dally over space any longer but must turn to time The world is closed in its space dimensions but is open in both directions in its time dimension Proceeding from 'here' in any direction in space we ultimately come back to 'here', but proceeding from 'now' towards the future or the past we shall never come across 'now' again There is no bending round of time to bring us back to the moment we started from In mathematics this difference is provided for by the symbol $\sqrt{-1}$, just as the same symbol crops up in distinguishing a closed ellipse and an open hyperbola

If, then, we are looking for an end of the world—or, instead of an end, an indefinite continuation for ever and ever—we must start off in one of the two time directions How shall we decide which of these two directions to take? It is an important question Imagine yourself in some unfamiliar part of space time so as not to be biased by conventional landmarks or traditional standards of reference There ought to be a signpost with one arm marked 'To the future' and the other arm marked 'To the past' My first business is to find this signpost, for if I make a mistake and go the wrong way I shall lead you to what is no doubt an 'end of the world', but it will be that end which is more usually described as the *beginning*

In ordinary life the signpost is provided by consciousness Or perhaps it would be truer to say that consciousness does not bother about signposts, but wherever it finds itself it goes off on urgent business in a particular direction, and the physicist meekly accepts its lead and labels the course it takes 'To the future' It is an important question whether consciousness in selecting its direction is guided by anything in the physical world If it is guided, we ought to be able to find directly what it is in the physical world which makes it a one way street for conscious beings The view is sometimes held that the 'going on of time' *does not exist in the physical world* at all and is a purely subjective impression According to that view, the difference between past and future in the material universe has no more significance than the difference between right and left The fact that experience presents space time as a cinematograph film which is always unrolled in a particular direction is not a property or peculiarity of the film (that is, the physical world) but of the way it is inserted into the cinematograph (that is, consciousness) In fact, the one-way traffic in time arises from the way our material bodies are geared on to our consciousness

> "Nature has made our gears in such a way
> That we can never get into reverse"

If this view is right, 'the going on of time' should be dropped out of our picture of the physical universe Just as we have dropped the old geocentric outlook and other idiosyncrasies of our circumstances as observers, so we must drop the dynamic presentation of events which is no part of the universe itself but is introduced in our peculiar mode of apprehending it In particular, we must be careful not to treat a past to-future presentation of events as truer or more significant than a future to-past presentation We must, of course, drop the theory of evolution, or at least set alongside it a theory of anti evolution as equally significant

If anyone holds this view, I have no argument to bring against him I can only say to him, "You are a teacher whose duty it is to inculcate in youthful minds a true and balanced outlook But you teach (or without protest allow your colleagues to teach) the utterly one-sided doctrine of evolution You teach it not as a colourless schedule of facts but as though there were something significant, perhaps even morally inspiring, in the progress from formless chaos to perfected adaptation This is dishonest, you should also treat it from the equally significant point of view of anti-evolution and discourse on the progress from future to past Show how from the diverse forms of life existing to-day Nature anti-evolved forms which were more and more unfitted to survive, until she reached the sublime crudity of the palæozoic forms Show

* This ambiguity is inseparable from the operation of counting the number of particles in finite but unbounded space It is impossible to tell whether the protons have been counted once or twice over

how from the solar system Nature and evolved a chaotic nebula. Show how, in the course of progress from future to past, Nature took a universe which, with all its faults, is not such a bad effort of architecture and—in short, made a hash of it."

Entropy and Disorganisation

Leaving aside the guidance of consciousness, we have found it possible to discover a kind of signpost for time in the physical world. The signpost is of rather a curious character, and I would scarcely venture to say that the discovery of the signpost amounts to the same thing as the discovery of an objective 'going on of time' in the universe. But at any rate it serves to discriminate past and future, whereas there is no corresponding objective distinction of left and right. *The distinction is provided* by a certain measurable quantity called entropy. Take an isolated system and measure its entropy S at two instants t_1 and t_2. We want to know whether t_1 is earlier or later than t_2 without employing the intuition of consciousness, which is too disreputable a witness to trust in mathematical physics. The rule is that the instant which corresponds to the greater entropy is the later. In mathematical form

dS/dt is always positive.

This is the famous second law of thermodynamics.

Entropy is a very peculiar conception, quite unlike the conceptions ordinarily employed in the classical scheme of physics. We may most conveniently describe it as the measure of disorganisation of a system. Accordingly, our signpost for time resolves itself into the law that disorganisation increases from past to future. It is one of the most curious features of the development of physics that the entropy outlook grew up quietly alongside the ordinary analytical outlook for a great many years. Until recently it always 'played second fiddle'; it was convenient for getting practical results, but it did not pretend to convey the most penetrating insight. But now it is making a bid for supremacy, and I think there is little doubt that it will ultimately drive out its rival.

There are some important points to emphasise. First, there is no other independent signpost for time; so that if we discredit or 'explain away' this property of entropy, the distinction of past and future in the physical world will disappear altogether. Secondly, the test works consistently; isolated systems in different parts of the universe agree in giving the same direction of time. Thirdly, in applying the test we must make certain that our system is strictly isolated. Evolution teaches us that more and more highly organised systems develop as time goes on; but this does not contradict the conclusion that on the whole there is a loss of organisation. It is partly a question of definition of organisation; from the evolutionary point of view it is quality rather than quantity of organisation that is noticed. But, in any case, the high organisation of these systems is obtained by draining organisation from other systems with which they come in contact. A human being as he grows from past to future becomes more and more highly organised—at least, he fondly imagines so. But if we make an isolated system of him, that is to say, if we cut off his supply of food and drink and air, he speedily attains a state which everyone would recognise as 'a state of disorganisation'.

It is possible for the disorganisation of a system to become complete. The state then reached is called thermodynamic equilibrium. The entropy can increase no further, and, since the second law of thermodynamics forbids a decrease, it remains constant. Our signpost for time disappears; and so far as that system is concerned, time ceases to go on. That does not mean that time ceases to exist; it exists and extends just as space exists and extends, but there is no longer any one-way property. It is like a one-way street on which there is never any traffic.

Let us return to our signpost. Ahead there is ever-increasing disorganisation. Although the sum total of organisation is diminishing, certain parts of the universe are exhibiting a more and more highly specialised organisation; that is the phenomenon of evolution. But ultimately this must be swallowed up in the advancing tide of chance and chaos, and the whole universe will reach a state of complete disorganisation—a uniform featureless mass in thermodynamic equilibrium. This is the end of the world. Time will *extend* on and on, presumably to infinity. But there will be no definable sense in which it can be said to *go* on. Consciousness will obviously have disappeared from the physical world before thermodynamical equilibrium is reached, and dS/dt having vanished, there will remain nothing to point out a direction in time.

The Beginning of Time

It is more interesting to look in the opposite direction—towards the past. Following time backwards, we find more and more organisation in the world. If we are not stopped earlier, we must

come to a time when the matter and energy of the world had the maximum possible organisation. To go back further is impossible. We have come to an abrupt end of space-time—only we generally call it the 'beginning.'

I have no 'philosophical axe to grind' in this discussion. Philosophically, the notion of a beginning of the present order of Nature is repugnant to me. I am simply stating the dilemma to which our present fundamental conception of physical law leads us. I see no way round it; but whether future developments of science will find an escape I cannot predict. The dilemma is this:—Surveying our surroundings, we find them to be far from a 'fortuitous concourse of atoms.' The picture of the world, as drawn in existing physical theories, shows arrangement of the individual elements for which the odds are multillions* to 1 against an origin by chance. Some people would like to call this non-random feature of the world purpose or design; but I will call it non-committally anti-chance. We are unwilling to admit in physics that anti-chance plays any part in the reactions between the systems of billions of atoms and quanta that we study; and indeed all our experimental evidence goes to show that these are governed by the laws of chance. Accordingly, we sweep anti-chance out of the laws of physics—out of the differential equations. Naturally, therefore, it reappears in the boundary conditions, for it must be got into the scheme somewhere. By sweeping it far enough away from the sphere of our current physical problems, we fancy we have got rid of it. It is only when some of us are so misguided as to try to get back billions of years into the past that we find the sweepings all piled up like a high wall and forming a boundary—a beginning of time—which we cannot climb over.

A way out of the dilemma has been proposed which seems to have found favour with a number of scientific workers. I oppose it because I think it is untenable, not because of any desire to retain the present dilemma. I should like to find a genuine loophole. But that does not alter my conviction that the loophole that is at present being advocated is a blind alley. I must first deal with a minor criticism.

I have sometimes been taken to task for not sufficiently emphasising in my discussion of these problems that the results about entropy are a matter of probability, not of certainty. I said above that if we observe a system at two instants, the instant corresponding to the greater entropy will be the later. Strictly speaking, I ought to have said that for a smallish system the chances are, say, 10^{20} to 1, that it is the later. Some critics seem to have been shocked at my lax morality in making such a statement, when I was well aware of the 1 in 10^{20} chance of its being wrong. Let me make a confession. I have in the past twenty-five years written a good many papers and books, broadcasting a large number of statements about the physical world. I fear that for not many of these statements is the risk of error so small as 1 in 10^{20}. Except in the domain of pure mathematics, the trustworthiness of my conclusions is usually to be rated at nearer 10 to 1 than 10^{20} to 1; even that may be unduly boastful. I do not think it would be for the benefit of the world that no statement should be allowed to be made if there were a 1 in 10^{20} chance of its being untrue; conversation would languish somewhat. The only persons entitled to open their mouths would presumably be the pure mathematicians.

Fluctuations

The loophole to which I referred depends on the occurrence of chance fluctuations. If we have a number of particles moving about at random, they will in the course of time go through every possible configuration, so that even the most orderly, the most non-chance configuration, will occur by chance if only we wait long enough. When the world has reached complete disorganisation (thermodynamic equilibrium) there is still infinite time ahead of it, and its elements will thus have opportunity to take up every possible configuration again and again. If we wait long enough, a number of atoms will, just by chance, arrange themselves in systems as they are at present arranged in this room; and, just by chance, the same sound-waves will come from one of these systems of atoms as are at present emerging from my lips; they will strike the ears of other systems of atoms, arranged just by chance to resemble you, and in the same stages of attention or somnolence. This mock Mathematical Association meeting must be repeated many times over—an infinite number of times, in fact—before t reaches $+\infty$. Do not ask me whether I expect you to believe that this will really happen.†

"Logic is logic. That's all I say."

So, after the world has reached thermodynamical equilibrium the entropy remains steady at its

* I use "multillions" as a general term for numbers of order $10^{10^{10}}$ or larger.

† I am hopeful that the doctrine of the "expanding universe" will intervene to prevent its happening.

maximum value, except that 'once in a blue moon' the absurdly small chance comes off and the entropy drops appreciably below its maximum value. When this fluctuation has died out, there will again be a very long wait for another coincidence giving another fluctuation. It will take multillions of years, but we have all infinity of time before us. There is no limit to the amount of the fluctuation, and if we wait long enough we shall come across a big fluctuation which will take the world as far from thermodynamical equilibrium as it is at the present moment. If we wait for an enormously longer time, during which this huge fluctuation is repeated untold numbers of times, there will occur a still larger fluctuation which will take the world as far from thermodynamical equilibrium as it was one second ago.

The suggestion is that we are now on the downward slope of one of these fluctuations. It has quite a pleasant subtlety. Is it chance that we happen to be running down the slope and not toiling up the slope? Not at all. So far as the physical universe is concerned, we have *defined* the direction of time as the direction from greater to less organisation, so that, on whichever side of the mountain we stand, our signpost will point downhill. In fact, on this theory, the going on of time is not a property of time in general, but is a property of the slope of the fluctuation on which we are standing. Again, although the theory postulates a universe involving an extremely improbable coincidence, it provides an infinite time during which the most improbable coincidence might occur. Nevertheless, I feel sure that the argument is fallacious.

If we put a kettle of water on the fire there is a chance that the water will freeze. If mankind goes on putting kettles on the fire until $t=\infty$, the chance will one day come off and the individual concerned will be somewhat surprised to find a lump of ice in his kettle. But it will not happen to *me*. Even if to-morrow the phenomenon occurs before my eyes, I shall not explain it this way. I would much sooner believe in interference by a demon than in a coincidence of that kind coming off; and in doing so I shall be acting as a rational scientist. The reason why I do not at present believe that devils interfere with my cooking arrangements and other business, is because I have become convinced by experience that Nature obeys certain uniformities which we call laws. I am convinced because these laws have been tested over and over again. But it is possible that every single observation from the beginning of science which has been used as a test, has just happened to fit in with the law by a chance coincidence. It would be an improbable coincidence, but I think not quite so improbable as the coincidence involved in my kettle of water freezing. So if the event happens and I can think of no other explanation, I shall have to choose between two highly improbable coincidences: (*a*) that there are no laws of Nature and that the apparent uniformities so far observed are merely coincidences; (*b*) that the event is entirely in accordance with the accepted laws of Nature, but that an improbable coincidence has happened. I choose the former because mathematical calculation indicates that it is the less improbable. I reckon a sufficiently improbable coincidence as something much more disastrous than a violation of the laws of Nature; because my whole reason for accepting the laws of Nature rests on the assumption that improbable coincidences do not happen—at least, that they do not happen in my experience.*

Similarly, if logic predicts that a mock meeting of the Mathematical Association will occur just by a fortuitous arrangement of atoms before $t=\infty$, I reply that I cannot possibly accept that as being the explanation of a meeting of the Mathematical Association in $t=1931$. We must be a little careful over this, because there is a trap for the unwary. The year 1931 is not an absolutely random date between $t=-\infty$ and $t=+\infty$. We must not argue that because for only $1/x$th of time between $t=-\infty$ and $t=\infty$ a fluctuation as great as the present one is in operation, therefore the chances are x to 1 against such a fluctuation occurring in the year 1931. For the purposes of the present discussion, the important characteristic of the year 1931 is that it belongs to a period during which there exist in the universe beings capable of speculating about the universe and its fluctuations. Now I think it is clear that such creatures could not exist in a universe in thermodynamical equilibrium. A considerable degree of deviation is required to permit of living beings. Therefore it is perfectly fair for supporters of this suggestion to wipe out of account all those multillions of years during which the fluctuations are less than the minimum required to permit of the development and existence of mathematical physicists. That greatly diminishes x, but the odds are still overpowering. The *crude* assertion would be that (unless we admit something which is not chance in the architecture of the universe) it is practically certain that at any assigned date the universe will be almost in the state of

* No doubt "extremely improbable" coincidences occur to all of us, but the improbability is of an utterly different order of magnitude from that concerned in the present discussion.

maximum disorganisation. The *amended* assertion is that (unless we admit something which is not chance in the architecture of the universe) it is practically certain that a universe containing mathematical physicists will at any assigned date be in the state of maximum disorganisation which is not inconsistent with the existence of such creatures. I think it is quite clear that neither the original nor the amended version applies. We are thus driven to admit anti-chance; and apparently the best thing we can do with it is to sweep it up into a heap at the beginning of time, as I have already described.

The connexion between our entropy signpost and that dynamic quality of time which we describe as 'going on' or 'becoming' leads to very difficult questions which I cannot discuss here. The puzzle is that the signpost seems so utterly different from the thing of which it is supposed to be the sign. The one thing on which I have to insist is that, apart from consciousness, the increase of entropy is the only trace that we can find of a one-way direction of time. I was once asked a ribald question: How does an electron (which has not the resource of consciousness) remember which way time is going? Why should it not inadvertently turn round and, so to speak, face time the other way? Does it have to calculate which way entropy is increasing in order to keep itself straight? I am inclined to think that an electron does do something of that sort. For an electric charge to face the opposite way in time is the same thing as to change the sign of the charge. So if an electron mistook the way time was going it would turn into a positive charge. Now, it has been one of the troubles of Dr. P. A. M. Dirac that in the mathematical calculations based on his wave equation the electrons do sometimes forget themselves in this way. As he puts it, there is a finite chance of the charge changing sign after an encounter. You must understand that they only do this in the mathematical problems, not in real life. It seems to me there is good reason for this. A mathematical problem deals with, say, four electric charges at the most; that is about as many as a calculator would care to take on. Accordingly, the unfortunate electron in the problem has to make out the direction of past to future by watching the organisation of three other charges. Naturally, it is deceived sometimes by chance coincidences which may easily happen when there are only three particles concerned; and so it has a good chance of facing the wrong way and becoming a positive charge. But in any real experiment we work with apparatus containing billions of particles—ample to give the electron its bearings with certainty. Dirac's theory predicts things which never happen, simply because it is applied to problems which never occur in Nature. When it is applied to four particles alone in the universe, the analysis very properly brings out the fact that in such a system there could be no steady one-way direction of time, and vagaries would occur which are guarded against in our actual universe consisting of about 10^{79} particles.

Heisenberg's Principle

A discussion of the properties of time would be incomplete without a reference to the principle of indeterminacy, which was formulated by Heisenberg in 1927 and has been generally accepted. It had already been realised that theoretical physics was drifting away from a deterministic basis; Heisenberg's principle delivered the knock-out blow, for it actually postulated a certain measure of indeterminacy or unpredictability of the future as a fundamental law of the universe. This change of view seems to make the progress of time a much more genuine thing than it used to be in classical physics. Each passing moment brings into the world something new—something which is not merely a mathematical extrapolation of what was already there.

The deterministic view which held sway for at least two centuries was that if we had complete data as to the state of the whole universe during, say, the first minute of the year 1600, it would be merely a mathematical exercise to deduce everything that has happened or will happen at any date in the future or past. The future would be determined by the present as the solution of a differential equation is determined by the boundary conditions. To understand the new view, it is necessary to realise that there is a risk of begging the question when we use the phrase 'complete data'. All our knowledge of the physical world is inferential. I have no direct acquaintance with my pen as an object in the physical world; I infer its existence and properties from the light waves which fall on my eyes, the pressure waves which travel up my muscles, and so on.

Precisely the same scheme of inference leads us to infer the existence of things in the past. Just as I infer a physical object, namely, my pen, as the cause of certain visual sensations now, so I may infer an infection some days ago as the cause of an attack of measles. If we follow out this principle completely we shall infer causes in the year 1600

for all the events which we know to have happened in 1930. At first sight it would seem that these inferred causes have just as much status in the physical world as my fountain pen, which is likewise an inferred cause. So the determinist thinks he has me in a cleft stick. If the scientific worker poking about in the universe in 1600 comes across these causes, then he has all the data for making a correct prediction for 1930; if he does not, then he clearly has not complete knowledge of the universe in 1600, for these causes have as much right to the status of physical entities as any of our other inferences.

I need scarcely stop to show how this begs the question by arbitrarily prescribing what we should deem to be complete knowledge of the universe in 1600, irrespective of whether there is any conceivable way in which this knowledge could be obtained at the time. What Heisenberg discovered was that (at least in a wide range of phenomena embracing the whole of atomic physics and electron theory) there is a provision of Nature that just half of the data demanded by our determinist friend might with sufficient diligence be collected by the investigators in 1600, and that complete knowledge of this half would automatically exclude all knowledge of the other half. It is an odd arrangement, because you can take your choice which half you will find out; you can know either half but not both halves. Or you can make a compromise and know both halves imperfectly, that is, with some margin of uncertainty. But the rule is definite. The data are linked in pairs and the more accurately you measure one member of the pair the less accurately you can measure the other member.

Both halves are necessary for a complete prediction of the future, although, of course, by judiciously choosing the type of event we predict we can often make safe prophecies. For example, the principle of indeterminacy will obviously not interfere with my prediction that during the coming year zero will turn up approximately $\frac{1}{37}$ of the total number of times the roulette ball is spun at Monte Carlo. All our successful predictions in physics and astronomy are on examination found to depend on this device of eliminating the inherent uncertainty of the future by averaging.

As an illustration, let us consider the simplest type of prediction. Suppose we have a particle, say an electron, moving undisturbed with uniform velocity. If we know its position now and its velocity, it is a simple matter to predict its position at some particular future instant. Heisenberg's principle asserts that the position and velocity are paired data; that is to say, although there is no limit to the accuracy with which we might get to know the position and no limit to the accuracy with which we might get to know the velocity, we cannot get to know both. So our attempt at an accurate prediction of the future position of the particle is frustrated. We can, if we like, observe the position now and the position at the future instant with the utmost accuracy (since these are not paired data) and then calculate what has been the velocity in the meantime. Suppose that we use this velocity together with the original position to compute the second position. Our result will be quite correct, and we shall be true prophets—after the event.

This principle is so fully incorporated into modern physics that in wave mechanics the electron is actually pictured in a way which exhibits this 'interference' of position and velocity. To attribute to it exact position and velocity simultaneously would be inconsistent with the picture. Thus, according to our present outlook, the absence of one half of the data of prediction is not to be counted as ignorance; the data are lacking because they do not come into the world until it is too late to make the prediction. They come into existence when the event is accomplished.

I suppose that to justify my title I ought to conclude with a prophecy as to what the end of the world will be like. I confess I am not very keen on the task. I half thought of taking refuge in the excuse that, having just explained that the future is unpredictable, I ought not to be expected to predict it. But I am afraid that someone would point out that the excuse is a thin one, because all that is required is a computation of averages and that type of prediction is not forbidden by the principle of indeterminacy. It used to be thought that in the end all the matter of the universe would collect into one rather dense ball at uniform temperature; but the doctrine of spherical space, and more especially the recent results as to the expansion of the universe, have changed that. There are one or two unsettled points which prevent a definite conclusion, so I will content myself with stating one of several possibilities. It is widely thought that matter slowly changes into radiation. If so, it would seem that the universe will ultimately become a ball of radiation growing ever larger, the radiation becoming thinner and passing into longer and longer wavelengths. About every 1500 million years it will double its radius, and its size will go on expanding in this way in geometrical progression for ever.

Science and Prediction

"PROPHECY", we are told, "is the most gratuitous of all forms of error", and long-distance forecasts have a way of going wrong, even when apparently firmly based upon all the available knowledge of the time Thus, Sir William Crookes predicted a world shortage of wheat for the present age, when in fact (owing to the unexpected success of science in fixing atmospheric nitrogen and making new fertilisers) there is an embarrassing surplus The real justification for making such forecasts is not that they are likely to be realised, but that they throw light upon the state of contemporary science, and may indicate where it requires supplementing This may be exemplified from the address of Sir Arthur Eddington presented in the present supplement

Before analysing Sir Arthur's basis of predictions concerning the end of the world, we may briefly consider earlier discussions of this topic At one time, such speculations had a theological basis, and often predicted a very unequal distribution of temperature, which in some regions would be excessively high In the nineteenth century, these were replaced by considerations concerning the loss of heat by the earth and the sun The earth was apparently cooling so rapidly as to leave insufficient time for biological evolution, and in a comparatively short time (from the evolutionary point of view) both earth and sun seemed doomed to experience a temperature which would be uniform and excessively low However, the date of this predicted catastrophe had to be put forward about a billion and a half years when radioactivity was discovered, for it revealed immense quantities of stored up atomic energy which could be changed into heat Another postponement was necessitated by the discovery of the convertibility of mass and radiation This gave the sun an enormously increased lifetime A period at least a hundred times more remote than before was offered by the astronomer's suggestion that in the interior of heavy atoms an electron may combine with a proton and release energy by their mutual annihilation But all this merely put off the evil day when a dying earth should at last fall into a dying sun and the whole universe, ever contracting, finally collapse in a single heap Sir Arthur Eddington, taking as his basis the second law of thermodynamics and recent developments of the cosmological theory of relativity, adopts the prediction as to the ultimate uniformity and lowness of temperature, but declares the universe to be expanding instead of contracting Possibly it will become a ball of radiation which doubles its size every 1500 million years, growing ever more and more attenuated

Let us consider the evidence for the physical laws underlying these predictions The cosmological theory of relativity may be considered as having arisen from the attempt to make the boundary conditions, as well as the differential equations expressing physical laws, independent of the choice of co ordinates Einstein in 1917 accomplished this by the drastic method of abolishing the boundary, and postulating a universe which was finite though unbounded (the analogue of the finite but unbounded surface of a sphere) An alternative theory was given by de Sitter, but, as was pointed out by Sir Arthur Eddington, neither of these theories could be accepted as corresponding to physical realities One contained matter but no motion, and the other motion but no matter No further progress was made for about ten years, when Lemaître obtained a new solution of the relativity equations This corresponded to an expanding universe, and it was afterwards shown that Einstein's and de Sitter's theories were limiting cases of this, one at the beginning of the motion and the other at the end, probably both unattainable The strong point of Lemaître's theory is that it offers an explanation of the observed redness of the spectra of many nebulæ, which is generally taken to mean that they are moving away from us at enormous speeds But it must not be forgotten that other explanations of this redness are possible Lemaître's cosmological theory holds the field for the present, but it is far from being thoroughly tested

The second law of thermodynamics is on a different footing Nothing seems better established than that it is impossible for a self acting system, unaided by an external agency, to convey heat from one body to another at a higher temperature Yet even here doubt may be felt as to whether this is without exception Millikan tells us that the intensely cold regions in the depths of interstellar space are the source of a very penetrating radiation, known as the cosmic rays These seem to be due to the building up of the more complex elements out of hydrogen In other words, the processes of disintegration and decay which are taking place elsewhere appear to be reversed here Let us not be too sure that the universe is like a watch that is always running down, there may be a rewinding The process of creation may not yet be finished

H. T. H. PIAGGIO.

Printed in Great Britain by R. & R. Clark, Limited, Edinburgh.

hills, Lanarkshire, in 1763 Given a good education, he became a student in Black's classes at the University of Edinburgh, but following in his father's footsteps, he entered the service of the Wanlockhead Mining Company near Leadhills Familiar with the steam engines of Newcomen and Watt, in 1786 he made a model steam carriage and in 1787 took out a patent for a new form of steam engine Through this he was brought into contact with Patrick Miller, the banker, who was desirous of trying a steam engine in one of the double-hulled boats with which he was experimenting To meet Miller's wishes, Symington constructed an engine with cylinders 4 in in diameter, which in October 1788 drove one of Miller's boats across the little Dalswinton Loch in Dumfriesshire at 4-5 miles an hour Next year a larger boat and a larger engine were experimented with, but the results were not very satisfactory and the matter was not pursued further The engine of 1788 happily was preserved and can be seen in the Science Museum, South Kensington It is the oldest marine engine in existence, and there are few older steam engines of any kind

The experiments of Miller and Symington had been preceded by those of Rumsey on the Potomac and of Fitch on the Delaware, and Fitch was the first in the world to form a steam boat company and to carry passengers His company, it is true, had but a short life, but from then onwards to the end of the eighteenth century there was probably never a time when one or other of the steam boat pioneers was not at work Symington's second opportunity came in 1801, when Thomas, Lord Dundas of Kerse, a governor of the Forth and Clyde Canal Company, instructed him to build a steam boat for use on the Canal The hull was constructed by Hart, of Grangemouth, and the *Charlotte Dundas*, as the boat was called, was 56 ft long and 18 ft wide There was a recess in the stern for a paddle wheel, the boiler was placed aft on the starboard side, and the engine on the port side To the uninitiated, the engine of 1788 might appear to have required more ingenuity to design than that of 1801 It is certainly far more complicated, but this was partly due to the steps Symington had to take to avoid the ramifications of Watt's patents which were in force In 1801 those patents had expired, and, free to use the ideas of his predecessors and to combine these in any way he thought best, Symington was able to construct an engine for the *Charlotte Dundas* which would almost meet modern requirements The engine was double-acting with one cylinder, and the piston rod drove the crank shaft of the paddle wheel direct through a crosshead and a connecting rod The air pump and condenser were placed below the cylinder, the former being worked by a bell crank lever

The running of the *Charlotte Dundas* quickly proved that Symington had produced a reliable and powerful engine, and the capacity of the boat was shown by her successfully towing two vessels of 70 tons each a distance of 19½ miles Convinced of the utility of the boat, Lord Dundas introduced Symington to the Duke of Bridgewater, who without much hesitation decided to adopt vessels similar to the *Charlotte Dundas* for the Bridgewater Canal and ordered the construction of eight steam boats Had the Duke lived but another year, there is little doubt that the boats would have been built and that to-day we should date the birth of steam navigation from the *Charlotte Dundas* and not from the *Clermont* and the *Comet* The Duke's death in 1803, however, led to the cancellation of the order, and about the same time the owners of the Forth and Clyde Canal, afraid of the effects of the wash caused by the *Charlotte Dundas*, laid her up on the mud near Bainsford Drawbridge, which became her grave She was never used again, and engine and hull alike have long since been destroyed

This proved the turning point in Symington's career and he never recovered from the disastrous set back to his fortunes When more than sixty years of age, he sought assistance from the Government and was granted two small sums, of £100 and £50 His death took place in London on Mar 22, 1831, and three days later he was buried in the churchyard of St Botolph, Aldgate His grave never bore a stone, but in 1903 a tablet to his memory was placed in the church by the late Lord Bearsted, who was then Sir Marcus Samuel and Lord Mayor of London A marble bust of Symington was unveiled in the Royal Scottish Museum in 1890 by Lord Kelvin

Though in his day neglected, Symington to-day is recognised as the designer of the first practical steam boat, and at the request of the Institute of Marine Engineers and the Newcomen Society, the vicar of St Botolph, Aldgate, has arranged to hold a special service to commemorate the centenary of his death This service will take place at 11 A M on Sunday, Mar 22, the hundredth anniversary of Symington's death, and an address on Symington's work will be given by Engineer Vice-Admiral Sir Robert Dixon

Obituary

MR H HARRIES

WITH the death of Mr Henry Harries on Feb 8, at the age of seventy-nine years, we lose one of the older generation of meteorologists Born on Jan 20, 1852, he entered the Marine Division of the Meteorological Office in 1875 In 1903 he was transferred to the Forecast Division, where he took regular duty as a forecaster In 1919 he returned to the Marine Division, where he held the post of assistant superintendent until his retirement in March 1920

Mr Harries' interest in meteorological matters extended beyond his official duties, however, especially along a number of curious bypaths of knowledge He was convinced that explosions in collieries were connected with high barometric

pressure and supported his thesis in a long letter to NATURE in 1887 (vol 36, p 437) He also developed the theory that some of the barometric depressions which visit the British Isles originate in tropical cyclones, and he actually succeeded in tracing the course of one such storm from the Philippines to Scandinavia, more than half way round the globe—no easy matter in 1882

The capacity for painstaking research which characterised this paper also marked Mr Harries' collection of occurrences of hail and thunder storms in Arctic regions, his study of the frequency, size, and distribution of hail at sea, and his paper on the great storm of November 1703, in which he brought to light some long-buried official records The same thoroughness, in a different direction, was shown in his paper on "The Eddy Winds of Gibraltar", in which he displayed great ingenuity in the use of simple methods of aerological investigation This paper was published in 1914 by the Royal Meteorological Society, of which he was a fellow from 1887 until 1914

DR FLORENCE BUCHANAN

BY the death of Dr Florence Buchanan on Mar 13, a familiar figure is removed from the laboratories at Oxford For the past ten years she had been handicapped by increasing blindness, but even so, occasional articles have appeared from her pen Previously she had carried out many interesting studies in the fields of zoology and physiology Her earliest papers, on the respiratory organs of decapods and on annelids, appeared in the *Quarterly Journal of Microscopical Science* while she was still a student at University College, London, and there the influence of Sir Ray Lankester turned her attention to zoological studies, particularly of the polychæts Later, with Sir John Burdon Sanderson at Oxford, she turned to physiological experiments upon the electrical response of muscle, recorded photographically by a capillary electrometer, and as a result of her investigations she was awarded several prizes, received the degree of D Sc from the University of London, and was made a fellow of University College

Throughout her physiological work, Dr Buchanan retained her first interest in animal life, and to a biologist some of her most striking researches were concerned with the frequency of the heart beat in small mammals and birds, with the varying rates of heart-beat in hibernating and waking mammals, and with the general problem of hibernation Heredity may have accounted for Dr Buchanan's scientific skill and enthusiasm, for she was a daughter of the late Sir George Buchanan, chief medical officer of the Local Government Board, and a sister of Sir George Seaton Buchanan and Lady Adam Smith, wife of the principal of the University of Aberdeen J R

THE death occurred on Sunday, Feb 15, of W G Robson, lecturer in natural philosophy in the United College of the University of St Andrews From 1892, when Mr Robson was appointed assistant to Prof A S Butler, he was almost continuously associated with the University either in St Andrews or Dundee During the War he was engaged in the Aircraft Instruments Department in London, and had charge of the Oxygen Research Laboratory His wide experience, kindly disposition, and his knowledge of mathematics, physics, and electrical engineering made him a most valuable member of the University staff

WE regret to announce the following deaths

Dr M W Beijerinck, founder and director of the Microbiological Institute at Delft, on Jan 1, aged seventy nine years

Prof G Gehlhoff, of the Technical Highschool, Berlin, president of the Deutsche Gesellschaft fur Technische Physik, vice president of the Deutsche Glastechnische Gesellschaft and a director of the Osram G m b H, who in recent years took a leading part in the development of glass technology in Germany and made a number of notable contributions from his own laboratory, died on Mar 12

Prof D Hepburn, C M G, professor of anatomy in the Cardiff Medical School of the University of Wales, formerly president of the Anatomical Society of Great Britain and Ireland, on Mar 10, aged seventy two years

Prof Carl Emil Hansen Ostenfeld, professor of botany and director of the botanical garden in the University of Copenhagen, on Jan 16, aged fifty-eight years

Prof Enrico Sereni, head of the department of physiology in the Stazione Zoologica, Naples, on Mar 1, aged thirty one years

Prof Otto Wallach, emeritus professor of chemistry in the University of Bonn, who specialised in the chemistry and industrial uses of the terpenes and was awarded the Nobel prize for chemistry in 1910, on Mar 1, aged eighty four years

News and Views

THE Council of the Royal Society has agreed to recommend for election as fellows of the Society the following seventeen candidates Percy George Hamnall Boswell, professor of geology in the Imperial College of Science and Technology, Alfred Joseph Clark, professor of pharmacology in the University of Edinburgh, Charles Davidson, assistant at the Royal Observatory, Greenwich, Reginald Ruggles Gates, professor of botany, King's College, London, Charles Stanley Gibson, professor of chemistry, Guy's Hospital Medical School, Hermann Glauert, Principal Scientific Officer, Royal Aircraft Establishment, Farnborough, Charles Robert Harington, reader in pathological chemistry in the University of London (University College Hospital Medical School), Isidor Morris Heilbron, professor of organic chemistry in the University of Liverpool, Sir Alexander Cruikshank Houston, Director of Water Examinations to the Metropolitan Water Board, Lieut -Col Sydney Price James, I M S, adviser on tropical diseases to the Ministry of Health, Charles Frewen Jenkin, lately professor of engineering science in the University of

Oxford, Stanley Wells Kemp, director of research, *Discovery* Expedition, Thomas Howell Laby, professor of natural philosophy, University of Melbourne, William Kingdon Spencer, palæontologist, Edward Charles Titchmarsh, professor of pure mathematics in the University of Liverpool, Wilfred Trotter, surgeon to University College Hospital, Miles Walker, professor of electrical engineering, University of Manchester

THE Dalton medal of the Manchester Literary and Philosophical Society, which was awarded to Sir J J Thomson on Mar 10 on the occasion of his visit to Manchester, was founded so far back as the year 1864, but, curiously enough, no allotment was made until 1898 The circumstances attending its early institution and production are somewhat obscure, at any rate it was a medallic gift to be adopted "for presentation on such occasions as the society may determine", a decision which left future bestowal an open matter, a point well seen in the awards, which have only occurred as follows Dr Schunck (1898), Sir Henry Roscoe (1900), Prof Osborne Reynolds (1903), Lord Rutherford (1919), Sir J J Thomson (1931) The medal is struck in bronze, the obverse bears the head of John Dalton, and on the reverse, within crossed laurel branches, is a sphinx, with accompanying legend, "Knowledge is Power" The first presentation of what was apparently an original Dalton medal was made on Mar 29, 1898, to Dr Edward Schunck, in "recognition of his series of researches on the natural colouring matters, with which he has enriched chemistry" Schunck had been a member of the Manchester Literary and Philosophical Society for fifty six years It may be recalled that on the occasion of the gift, Sir Joseph Hooker attended to receive the Wilde gold medal, whilst Sir Michael Foster delivered the Wilde lecture, with the title "On the Physical Basis of Psychical Events"

THE discontinuance of a medallic gift by a scientific society is unusual This has been the case, however, with the Wilde gold medal of the Manchester Literary and Philosophical Society In 1895, Dr Henry Wilde, a generous benefactor in many directions, established a fund, part of which was to be devoted to the annual award of a gold medal for distinguished services to science and philosophy The first medal was given in 1896 to Sir George Stokes for "pre eminent services to mathematical and physical science" Sir George visited Manchester in the following year, received the medal, and gave an address entitled "The Nature of the Röntgen Rays" The final gift of the kind was made in 1908 to Sir Joseph Larmor Referring to the article on the sesqui centenary of the foundation of the Manchester Literary and Philosophical Society in NATURE of Mar 14 (p 408), it has been pointed out by a correspondent that the Copley medal of the Royal Society was never awarded to John Dalton Dalton received the Royal Society's Royal medal in 1826, the first presented at the time of institution

THE election on Mar 9 of Prof Elie Cartan to the seat of the late Paul Appell in the Paris Academy of Sciences has added a prominent mathematician to the distinguished body of men of science of the Quai Conti Prof Cartan has specialised in the theory of groups and in higher geometry, and has developed these fundamental branches of mathematics in unexpected and far reaching directions We still remember the deep impression he made at the International Congress of Mathematicians in Bologna, when he showed how to determine a complete orthogonal system of functions in any Riemannian space with a positive curvature and symmetrical with reference to each of its points, and how to derive a geometrical representation of these series of fundamental functions by means of a special type of isometrical transformations Indeed in his numerous memoirs on these abstruse topics, Prof Cartan has given a remarkable generalisation to the Riemannian spaces, thus preparing the way to subsequent developments in natural philosophy

IN Newtonian mechanics, as is well known, gravitation has no influence on measurements as such In Einstein's universe, however, all measurements follow so closely the structural character of the gravitational field in which they are immersed, that a knowledge of the geometry of that field is equivalent to a knowledge of its physical properties, so that mechanics is implied in geometry again, as was the case during the golden period of Greek science It appears necessary, then, to labour in detail the manifold interpretation of the notion of space underlying the geometrical and physical description of the universe The curved space discovered by Riemann in 1853 which found its practical application in 1916, has to be itself generalised and enlarged if the future claims of theoretical physics have to be satisfied In this connexion "Cartan's spaces", by reason of their greater generality and completeness, are of supreme importance This was a new revelation to some of us who listened to his illuminating exposition at the International Congress of Philosophy at Naples in 1924, when Prof Cartan spoke of the torsional properties of space and the difficulties created by magnetic phenomena in the single vectorial representation of material particles The practical value of his intuitions has been confirmed since by the implications of De Broglie's wave mechanics, which seems to demand a more complex theory of groups for its geometrical interpretation As a mathematician, Prof Cartan has had a distinguished career Born in 1869, he studied at the École Normale Supérieure of Paris, and took his doctor's degree in 1894 He now occupies the chair of higher geometry, which was held previously by Darboux, at the University of Paris His numerous mathematical memoirs earned for him, last autumn, the Grand Prix of £400 of the Paris Academy of Sciences

AFTER a keen debate in the House of Commons, on Mar 16, Clause 4 of the Representation of the People Bill, which had been before the House in committee, was defeated by 246 votes to 242 The special claim of Queen's University, Belfast, was first brought forward by Mr Ross and supported by Col Sinclair, pro chancellor of Queen's University and its representative in Parliament This claim, however

was rejected by 178 votes to 168 The motion for the deletion of Clause 4 from the Bill was presented by Lord Hugh Cecil He analysed the question of equalitarian democracy, which is based on the 'one vote, one value' theory, and declared it does not and cannot exist He then appealed to the members not to spoil the tradition of true representation Major Church opposed his own party by strongly supporting this appeal He considers it intolerable that this bill should suggest that university education is not of special value, especially in view of the fact that the universities are no longer class preserves and produce advisers to governments and leaders of science and industry Mr Clynes refused the appeal for a free vote, pointing out that, at least, there is no justification for giving university voters twice the representation of other voters He pointed out that university members have shown little special political capacity The Government was also supported by Sir Herbert Samuel

IN a pamphlet entitled "A National Policy" (London Macmillan and Co, Ltd 6d), describing the programme advanced by Sir Oswald Mosley, M P, there are some references to scientific research which, without trenching on questions of party politics, it may be of interest to summarise No task, it is argued, is of more vital importance than that of mobilising our great scientific resources and attainments Great Britain's industrial future depends on the rapid and effective adoption of new scientific results more than upon any other single factor Our high degree of industrialisation, our unrivalled technical experience, the skill of our workers, our great resources of scientific ability and devotion, give us the opportunity to maintain our lead indefinitely What is chiefly lacking is the effective co ordination and application of our resources The work of the Department of Scientific and Industrial Research is commended, but it is said that the scale on which it is allowed to operate is too limited A method must be adopted by which new devices and inventions can be carried through the difficult intermediate stage between successful laboratory results and commercial exploitation At present, the Department can only test inventions at the owner's expense and issue a report on the results A certain maximum sum should be set aside each year for the Department's use for the development of a small number of selected inventions which after making a suitable financial arrangement with the patentee, should be taken right out of the laboratory stage and put on the market under public auspices

SIR OSWALD MOSLEY also suggests the fostering of inventions and the extension of agricultural and medical research, while an organised attempt might be made to standardise many of the basic products of industry for mass production purposes, comparable to Mr Hoover's remarkable campaign in the United States of America The establishment of new industries under the direction of a National Investment Board is advocated where these industries might be of great value to the community though as yet they are not in a position to attract private enterprise Thus, coal carbonisation appears to be insufficiently profitable to attract an adequate amount of private capital, but its establishment, it is suggested, might be justified on grounds of public policy, because (1) it might mean the 'salvaging' of a large amount of the community's capital which has been sunk in coal mining and would be rendered profitable again if a new market for coal were created, (2) it would lessen our dependence on imported oil fuel, (3) a smokeless fuel would be produced, and (4) the new work available in the coal fields would mean a saving in unemployment relief

THE Council of the Linnean Society of London has reached an important decision with regard to the publication of the *Proceedings* of the Society The *Proceedings*, instead of being published in an annual volume, are being issued sheet by sheet of 16 pages, and in this way an abstract of a paper read before the Society may be in the hands of fellows and of the public between three and eight weeks after the reading of the paper Each sheet of the *Proceedings* so issued will rank as a publication on the date of issue, so that the utmost is being done to conserve for contributors to the Society the priority of their discoveries, provided, of course, that in the case of new species a sufficient diagnosis accompanies the publication of the new name This precaution has not been taken, for example, in the case of a new species of *Hoplophorus* described in a recent issue, so that the advantage of early publication is lost in this case The importance in time of the arrangement which has now come into force is well illustrated by the first sheet of the new issue The *Proceedings* of Nov 20, 1930, were issued on Dec 17, whereas the annual volume issued in January 1931 contains reports of 'proceedings' so far back as Nov 7, 1929 Arrangements have been made whereby fellows, foreign members, and associates who still wish to possess the complete *Proceedings* in book form may obtain a copy each year at half the published price

THE Belfast Naturalists' Field Club, for some time past, has had under consideration the advisability of making a survey of the antiquities of that part of Northern Ireland covered by it and its affiliated societies Both the number and character of these antiquities and the risks to which the better known are exposed in modern conditions have been judged to make the matter one of such importance that the authorities of the Field Club have appointed a special committee to deal with it Members and others have been asked to co operate with the Committee by sending in lists, with full particulars, of any antiquities in their neighbourhood, especially those which are not included in the Ordnance maps Plans, sketches, and photographs are to be included, with a statement of exact position The topographical and full bibliographical details will be indexed and made available for consultation by students The scheme will cover buildings, monuments, and other remains of both historic and prehistoric times The chairman of the Committee is Mr H Albert Campbell, and the honorary secretary, Miss M Gaffikin

THE course of popular lectures on the native races of the British Empire given under the auspices of the Royal Anthropological Institute came to an end for the current session on Mar 11 with Mr E Torday's lecture on "The Things that Matter to the African" Mr Torday's lecture was a subtle but most illuminating interpretation of native life and tradition in West Africa, in which he showed that the frivolous, light hearted individual of many travellers is far from being the real man In fact, he appears to be something of an opportunist, for, while bowing to the domination of the sultanates, he has, at heart and in actual practice, remained a thorough democrat, in accordance with his long established tradition The case was well argued and convincingly supported by a wealth of detailed evidence which covered both religious belief and social custom Full justice was done to the remarkable but too little known character and influence of the women Mr Torday's conclusion that the West African is capable of concerted and persevering action when he aims at social ideals, taken with what he said in the body of his lecture, is both a warning and a guide to our administrators For it would appear that under the impact of European influences, a new culture is shaping which will differ from that of the past, but in which our share will depend very much upon our sympathetic understanding of native tradition We trust that Mr Torday's lecture will be given permanent form, for it is, without question, one of the most important pronouncements on the West Africans which has been made in recent years

INTERNATIONAL telephony has made wonderful progress during the past year At the beginning of 1929 radio telephony provided daily telephone service to more than twenty-six countries In 1930 the total of international connexions wholly or partly effected through radio telephony was increased to 177 The most important groups of connexions can be divided into three classes, the first one linking North and South America This group connects the United States, Canada, Cuba, and Mexico on one side with the Argentine, Chile, and Uruguay on the other The second group involves three new channels between Europe and South America They operate from Paris, Berlin, and London to Buenos Aires Land line connexions bring a total of twenty other countries into these circuits The third group involves the London Sydney circuit—a distance of 9192 miles These circuits connect most of the telephone users of the United States, Canada, Mexico, Great Britain, Hungary, and Italy with Australia Many more lines are being constructed, including one connecting the United States and Australia directly Spectacular conversations have been held from an aeroplane over the city of Buenos Aires with points in the United States, with the s s *Majestic* on the high seas, and with Sydney, Australia, a distance of 14,000 miles A conversation has also been transmitted round the world from Schenectady and then broadcast According to *Electrical Communication* for January, the international telephone directory (A T 1) for 1929 contained about 12,000 entries from 1485 towns in 27 different countries, the 1930 edition contains more than 50,000 entries from 2718 towns in 38 countries

THE tenth annual report of the Electricity Commissioners, which has just been published, shows clearly that the electric supply industry in Great Britain has been little if at all affected by the almost universal trade depression Dividing the country into regional districts of supply, linking up all the efficient large power stations, and gradually eliminating where possible the less efficient stations, is leading to a better utilisation of our coal resources The total number of units generated in the year ending in March 1921 was 5167 million units and the fuel consumption was 7 356 million tons For the year which ended in March 1930, the total number of units generated was 11,961 million, with a fuel consumption of 10 141 million tons It will be seen that although the number of units generated has been doubled, the consumption of coal has only increased by about 50 per cent Last year was noteworthy because of the continued expansion of the supply and the many schemes that are being put in hand for the improvement and further extension of public supplies The steady growth of the domestic supply has had a stabilising effect on the industry The units generated last year show an increase of 10 per cent of the number generated in the preceding year A number of small stations have been erected in isolated districts On the estimated population of Great Britain (44 5 millions) the sales of electrical units represent 193 units per capita, as compared with 171 in the previous report The question of rural development is discussed and it is pointed out that the prospects are favourable in certain cases

THE prize for 1930 for an improvement in the science or practice of navigation offered by the Royal Society of Arts, under the terms of the Thomas Gray Memorial Trust, has been awarded to Messrs Charles A Stevenson and David Alan Stevenson, of Edinburgh, for their invention of the talking beacon installed at Cumbrae Lighthouse The beacon, to which reference was made in NATURE of Jan 24, p 138, consists of an ingenious combination of fog signal and wireless transmitter The fog signal consists of three blasts followed by a short silence and then two further blasts At the same time, on a wireless receiver, a listener hears (*a*) the name of the beacon in speech (Cumbrae), (*b*) the three blasts of the fog signal, (*c*) counting in speech, in cables and sea miles up to five miles, and (*d*) the two blasts of the fog signal This is followed by a silent interval lasting twenty-seven seconds and is then repeated Immediately before each mile is spoken a bell is sounded The distance which the observer hears in his receiver, coinciding with the end of the third blast heard through the air, gives him the distance of his ship from the lighthouse The spoken words in the signal come from a gramophone record on a turn table, which is engaged and disengaged by means of a clutch with another turn-table kept constantly revolving by air turbine or motor The Council of the Royal Society of Arts is offering this year another prize of £100 to any

person who may bring to its notice a valuable improvement in the science or practice of navigation proposed or invented by himself in the years 1930 and 1931, and a prize of £100 for an essay on "The Stability of Ships, with special reference to the particulars which should be supplied by Shipbuilders, and also the value of any mechanical devices for ascertaining the M G, with which you are acquainted" Claims and essays must reach the Secretary, Royal Society of Arts, John Street, Adelphi, London, W C 2, not later than Dec 31, 1931

AT a conference at the Birmingham section of the British Industries Fair, Dr C H Lander, Director of Fuel Research, discussed the "Gas Industry in relation to British Fuel Problems" He stressed the importance of its contribution to the smoke problem, as a purveyor of smokeless fuels, to the domestic heating problem, and to the problem of obtaining oil and petrol from coal The carbonisation industries produce solid, liquid, and gaseous fuels and so all their problems are related and need to be considered together The current abundance of liquid fuels should not blind us to the possible future need for deriving supplies from coal The gas industry is well placed for marketing all the products of the carbonisation and hydrogenation of coal or its products In view of the potential contribution of the carbonisation industries to the reduction of smoke Dr Lander pleaded for collaboration of the gas and coking industries in the utilisation and marketing of their products Sir Arthur Duckham contrasted the potential contribution of the gas industry to the fuel problems of Great Britain with the legislative shackles imposed on its development, the restrictions placed on the use of gas by some local authorities, arising from an imperfect grasp of fuel problems by the general public and even by our legislators

THE first number of vol 3 of the *Collection of Czechoslovak Chemical Communications* (Jan Feb 1931) is a special issue dedicated to the memory of Prof František Wald, who died suddenly in October of last year His chief contributions to the advancement of science in central Europe were outlined in the obituary notice which appeared in NATURE for Jan 10, p 64 Had he lived Prof Wald would have attained seventy years of age last January, and the original intention of the editors of *Collection* was that this issue should have been a jubilee number in his honour Right up to the time of his death, Wald was engaged in elaborating his phenomenalistic theory of phases and stoichiometry These views are embodied partly in an article by his friend Dr A Kříž, and partly in a hitherto unpublished article by Wald himself, entitled "Foundations of a Theory of Chemical Operations" From these, it is clear that he disregarded much of the atomic theory and his definitions of elements and compounds do not coincide with those accepted generally His ideas attracted the attention of Prof Wilhelm Ostwald, whose friendship he enjoyed and who included him among the "Great Men of Science" Prof Wald was for many years chief chemist to an important metallurgical undertaking at Kladno, and among his seventy contributions to various scientific periodicals are several dealing with the adaptation of standard methods of chemical analysis to the special needs of metallurgy, especially to the evaluation of ores and the analysis of alloys In addition to appreciative articles on Wald's life and work, this special number of the Czechoslovak *Collection* contains several other articles of outstanding merit, including an account of some iron carbon silicon alloys (by Drs Kříž and Poboříl) and further polarographic studies with the dropping mercury cathode by Prof Heyrovský and collaborators, who find that in acid solution, nitric oxide is reduced to ammonia at a potential of 0 77 volt from that of the normal calomel electrode

WE have received a copy of the Subject Index to volumes 1 to 60 of the *Journal of Physiology*, which has been prepared by Dr J G Priestley, of Oxford The Physiological Society recently published a history of its first fifty years, written by Sir Edward Sharpey Schafer, and an author index to the first sixty volumes has also been issued These three volumes cover an important period in the history of physiology, a period which has seen its development into the science of to day *An important part of this development is* represented by the papers appearing in the first sixty volumes of the *Journal* The index has been made as complete as possible thus, where a subject can be considered from more than one point of view, entries referring to each of them are given In addition, the species on which the observations were made is also noted It runs to upwards of two hundred pages, and is published by the Cambridge University Press as a supplement to the first number of volume 71 of the *Journal of Physiology*, issued in January

THE Ministry of Agriculture desires to notify poultry farmers that it is now issuing a fowl pox vaccine at a charge of one penny per dose, with a minimum charge of 2*s* 6*d* covering a supply of 30 doses, with an instrument and brush for application The vaccine has been extensively tested, it is free from danger, and causes no constitutional disturbance It confers definite immunity of at least four months' duration Cash must be enclosed with each order, which should be addressed to the Director, Ministry of Agriculture and Fisheries Veterinary Laboratory, New Haw, Weybridge, Surrey The Ministry has also issued a bulletin (No 26) on Johne's disease, which gives a full account of this important disease of cattle The bulletin, price 3*d* post free, may be obtained from the Ministry of Agriculture and Fisheries, 10 Whitehall Place, London, S W 1

At the annual general meeting of the Society of Public Analysts held on Mar 4, the following officers for the year 1931 were elected *President*, Dr J T Dunn, *Hon Treasurer*, Mr E B Hughes, *Hon Secretary*, Mr F W F Arnaud

AMONG recent appointments made by the Secretary of State for the Colonies to the Colonial Agricultural Service are the following Mr H R Surridge, as agricultural officer, Fiji, and Mr H E Box, as entomologist, Antigua, Leeward Islands

SIR ARTHUR SMITH WOODWARD will deliver the Huxley Memorial Lecture at the Imperial College of

Science and Technology, South Kensington, on Monday, May 4, at 4 P M His subject will be "Modern Progress in Vertebrate Palæontology"

AT the annual meeting of the Geological Society of London held on Feb 21, the following officers were elected *President* Prof E J Garwood, *Vice Presidents* Mr J F N Green, Prof J W Gregory, Dr H H Thomas, and Prof W W Watts, *Secretaries* Mr W Campbell Smith and Prof W T Gordon, *Foreign Secretary* Sir Arthur Smith Woodward, *Treasurer* Mr F N Ashcroft

THE Masters' Memorial Lectures of the Royal Horticultural Society will be delivered in the lecture room of the Society's new hall in Greycoat Street, Westminster, on Wednesday and Thursday, April 8 and 9, at 3 30 P M, by Prof Erwin Baur, on "New Scopes and New Methods of Plant Breeding" and "The Problem of Evolution" Sir Daniel Hall and Sir Frederick Keeble will take the chair on these occasions

IT is announced by Northern News Services, Ltd, that Dr Hjalmar Broch director of the marine biology station of the University of Oslo, has been appointed by the Jugoslav Government to be director of the Institute of Deep sea Research and Fishery Investigations in the Adriatic The Jugoslav institute is being built at Split (Spalato), where all branches of science concerning deep sea research will be represented, including zoology, botany, and oceanography Local methods of fishing will also be investigated, with the view of modernising and rationalising these

A NEW article of association of the Royal Zoological Society of New South Wales, giving the council power to confer the title 'fellow' on any member or associate member of the Society who has rendered distinguished service to Australian zoology, has recently been formulated The council has conferred this title upon Dr R J Tillyard, H J Carter, W W Froggatt, T Iredale, A F Basset Hull, and T C Roughley, all of whom have contributed largely to scientific journals articles dealing with the various branches of Australian zoology The title is purely an honorary distinction

ACCORDING to the records obtained at Kew Observatory, the epicentre of the destructive earthquake which occurred in the Balkans at 1 h 50 m G M T on Mar 8 was near 41° N, 21° E The disturbance was about four times as violent as the shock which occurred in the same region at 0 h 16 m G M T on Mar 7 According to a revised estimate, the position of the epicentre of this earlier shock is 42° N, 23° E The earthquake which was felt in Japan on Mar 9 was recorded as a large disturbance at Kew Observatory A United States Coast and Geodetic Survey broadcast message gives the epicentre as 43° N, 140° E

ON Mar 13, Sir Frederick Gowland Hopkins, president of the Royal Society, unveiled, in one of the principal laboratories of the London School of Hygiene and Tropical Medicine, a memorial plaque in memory of the late Lord Wandsworth, who left a sum of £10,000 to found a scholarship for the promotion of medical research in one of the London medical schools The ceremony was performed in the presence of Sir William Hamer and Dr E Deller, Principal of the University, and others, during an official inspection of the School by the University of London In unveiling the tablet, Sir Gowland Hopkins expressed the hope that the work already done and the opportunities for the future which the scholarship afforded would be an abiding source of inspiration

THE Association of British Chemical Manufacturers has issued an "Index to Acts of Parliament and Statutory Rules and Orders affecting the Chemical Industry" Copies of this publication (price 2s net) may be obtained from W Heffer and Sons, 4 Petty Cury, Cambridge

SOME years ago, Dr Marie Stopes suggested that coital interlocking between the glans penis and the cervical canal occasionally occurred in man The phenomenon was, on anatomical grounds, scarcely credited (see NATURE, Oct 25, 1924, p 601, and Nov 15, 1924, 719) Dr Stopes now states (*C B C Bull*, No 2 1930) that the occurrence has been confirmed in 48 cases attending the Clinic for Constructive Birth Control and in others, 59 cases in all

THE Kodak Research Laboratories have just issued the thirteenth volume of abridgments of their scientific communications published in 1929 There are 37 of them in the volume, by 32 authors The subjects include physical photographic, and physiological optics, organic, physical, and colloid chemistry, photographic theory, and practical photography The abridgments are very full, giving all the essential details of the original papers

THE winter, 1930–31, issue of *The Fight against Disease*, the quarterly journal of the Research Defence Society, contains an article by Dr J H Burn on the use of animals for the standardisation of remedies, in which he points out that animal tests of activity are necessary not only for antitoxins and insulin but also for the arsenobenzenes An account is given of the debate in the House of Commons upon Commander Kenworthy's Bill to prevent the application of public money to vivisection experiments, which suffered the unusual fate of being refused a first reading

As a result of long standing trials, the National Institute of Agricultural Botany at Cambridge is well qualified to give reliable advice to farmers, and, as is pointed out by the Institute, the selection of the right variety of a crop may make all the difference between success and failure The publication of *Farmer's Leaflets* Nos 2, 3, 4, and 5, dealing respectively with cereals for spring sowing, potatoes, lucerne, and sugar-beet, should, therefore, prove of immediate benefit to the farming community The leaflets may be obtained post free on application to the Institute at Cambridge

UNDER the title of "Canada 1931", the Dominion Bureau of Statistics has published a handbook of the present conditions in Canada (Ottawa Dominion

Bureau of Statistics London High Commissioner for Canada) The small volume supplements the larger and more purely statistical "Canada Year Book" and gives enough comparative statistics to present a survey of most aspects of Canadian activity The reviews of agriculture, mining, and the development of water power are useful summaries A statistical appendix gives tabulated figures for the last ten decades in population, production, trade, and other matters There is also a list of official sources of information relating to Canada

Applications are invited for the following appointments, on or before the dates mentioned —A male fishery officer in the Fisheries Department of the Ministry of Agriculture and Fisheries—The Secretary, Ministry of Agriculture and Fisheries, 10 Whitehall Place, S W 1 (Mar 31) A biochemical assistant at the Hannah Dairy Research Institute, Auchincruive, Ayr—The Secretary, Hannah Dairy Research Institute, Auchincruive, Ayr (April 1) A junior technical examiner in the Lands Branch of the War Department —The Secretary, Civil Service Commission, Burlington Gardens, W 1 (April 16) A head of the science and engineering department of Highgate School—The Headmaster, School House, Highgate (May 10) An adviser in entomology for the Bristol Province under the Advisory Scheme of the Ministry of Agriculture and Fisheries—The Acting Registrar, The University, Bristol

Our Astronomical Column

The Corona without an Eclipse —M B Lyot's experiments with a sensitive polarimeter from the summit of the Pic du Midi, which is 9439 feet high, undoubtedly indicate the most hopeful means of observing the corona without an eclipse They are fully described in a bulletin dated Feb 14 issued by Science Service, Washington, D C A screen was used to cover the image of the sun's disc, and the prominences were then visible without the aid of a spectroscope The polarised light that he ascribes to the corona can only be traced for 3′ or 4′ above the sun's limb, so that the method only extends to the bright inner zone of the corona It is only observed in one position angle at a time, but by rotating the instrument round the sun's limb, it can be studied in all position angles Dr Deslandres is hopeful that it may be possible to photograph the images thus obtained The article recalls that François de Plantade, an assistant of Cassini, used the Pic du Midi for astronomical observations two centuries ago It also refers to the attempts of Prof Hale and Dr Steavenson to photograph the corona from high mountains, they did not, however, employ a polarimeter A complete check of the new method will be afforded when the moon is very near the sun, but not actually encroaching on the disc, if the method is sound, the dark disc of the moon should be discernible

The System of ξ Ursæ Majoris —This has long been known as an interesting double star with a period of 59 8 years, it has been followed through more than a revolution In 1905, Norlund detected an oscillation in the bright star with a period of 22 months, indicating that it has a close companion The fainter star was found to be a spectroscopic binary, with a period of 9 8 days, by the Lick observers in 1918 *Lowell Observatory Bulletin* 432 contains a discussion of the spectroscopic orbit by L Berman The discussion is complicated by the double orbital motion, the light time changes considerably during the description of the large orbit The 22 month orbit is turned nearly edgewise to us, and observers are asked to watch for a possible eclipse on Feb 4 or 5, 1932 We see the 9 8 day orbit nearly fully open, so the radial motion in it is small A very accurate parallax can be derived from a combination of the data, the adopted value is 0 126″, giving a distance of 26 light-years The combined mass of the brighter pair is 1¼ sun, that of the fainter pair is equal to the sun Both the visible components are about 1¼ times as dense as the sun The semi major axis of the 9 8 day orbit is 7,319,500 km, that of the 59 8 year orbit is about 20 astronomical units The spectrograms were measured by Mr Berman and Miss Hobe, they determined their personal equations by measuring spectrograms of Venus, the radial velocity of which is accurately known

Annuaire Astronomique Camille Flammarion, 1931 —This useful almanac (Observatoire de Juvisy, 12 francs) contains details of the positions of sun, moon, and planets, diagrams of the orientation of the solar equator in different months, data of all oppositions of Mars up to 1956, elements of Pluto with a diagram of its orbit and details of the two total lunar eclipses of 1931, which are both visible in England and France There is an excellent table of the elements of the orbits of periodic comets, compiled by M Baldet it includes comet Schwassmann Wachmann III (1930 *d*) There are also meteorological data and many useful tables of physical constants One notes the interesting fact that Mt Canigou can be seen from Marseilles projected upon the setting sun on certain days in February and October, the distance is 253 km, and the straight line joining the points is 120 m below the sea at the middle point, the visibility depends on refraction

A table of Easter up to 2319 may interest some readers One notes that Easter occurs in March once in 4½ years, it will not occur on Mar 22 (its earliest date) until 2285 It is, of course, assumed that the present mode of reckoning will be continued

Report of the Leyden Observatory for 1930 —The Report begins with acknowledgment of the gift of 110,000 dollars from the Rockefeller Foundation It is being used for the construction of a photographic equatorial of 40 cm aperture, which will be erected at Johannesburg, thus strengthening the connexion between Leyden and the Union Observatory Dr van den Bos has now become chief assistant at the Union Observatory Prof Hertzsprung and Mr van Gent are there temporarily

The meridian circle at Leyden was used for observation of the Eros reference stars The proper motions of the reference stars in the selected areas are being discussed, also those of stars in the Pleiades in connexion with Prof Hertzsprung's investigation Mr Kuiper has observed double stars with the 10-inch refractor on 63 nights

Mr van Gent has photographed several southern fields with the Franklin Adams camera, and has detected 82 known and 28 new minor planets Prof de Sitter and Dr Oort have investigated the radial velocities of the spiral nebulæ in relation to the theory of relativity and the rotation of the galaxy

Research Items.

The Society Islanders.—A study of the physical characters of the Society Islanders by H. L. Shapiro, and based upon material collected in the field on the Bayard Dominick Expedition by S. Craighill Handy and Willowdean C. Handy, is published in vol. 11, No. 4, of the *Memoirs of the Bernice P. Bishop Museum*, Honolulu. Eighteen characters were examined and fifteen indices calculated on two hundred and two individuals. The measurements of 153 only are included here, as 49 were excluded on the ground of non-Polynesian admixture. From a study of the distribution of these characters, which show bi-modal and multi-modal curves common to both sexes, it is concluded that there is heterogeneity in the population. The impression of massiveness and size is borne out by the measurements. The stature of 171.35 cm. places them among the tallest people in the world. The head is of medium length and of more than medium width, giving an index markedly brachycephalic. Both face height and width are large, producing a massive face. The forehead, however, is narrow, giving the distinctive character associated with the Polynesian. The nasal index is mesorhine; but the average dimensions are considerable, though they do not equal the average of the Samoans and Tongans. In bodily proportions and size the Society Islanders are relatively large. In general, the women display the same development as the men. Most of the Islanders have black hair. There are no blondes; but 13.14 per cent of the men and 15.15 per cent of the women have reddy-brown hair.

Tribes of the White Nile Province.—Some notes digested from reports and essays of members of the administrative staff by Mr. J. A. Reid are given in *Sudan Notes and Records*, vol. 13, pt. 2. The information has been collected since 1924. For practical purposes the province is divided into three areas: (1) the Kawahla group, (2) the Baggara group, and (3) the rest. The Kawahla group, the Hassania, Huseinat, and Kawahla proper, occupy the Geteina district and the riverain part of Dueim and Kawa, the first two being the predominant partners. They are now a river-dwelling, semi-nomadic folk, spending most of their time near the Nile, except when they go inland to cultivate their rainland and seek green pasture for their animals. As soon as the rains are over, they start cultivating the river flats and bring their animals to the water, where they remain until the next rains. They acquired their present *dâr* by conquest. Though the land must have been held in tribal holding originally, individual ownership developed rapidly. Blood money, originally paid in camels, as they owned no cattle, is now paid in cattle or ready money. The Baggara group extend from the southern end of the province, just south of Kawa, to the Upper Nile boundary. They are, in a general sense, the semi-nomadic Arabs whose business in life is cattle breeding and who ride on bulls, while they leave to slaves and others the cultivation of the ground. Even with extensive sheep owners, the flocks are of comparatively recent origin and are soon exchanged for wealth in cattle. During the rains, the Baggara move from the river and wells, the extent of their migrations being governed by the fly. Practically all cultivate, but it is not their main object. Land, to begin with, belonged to the tribes, being held by the chief as trustee; but there were very definite rights of usufruct. When, on the lighter lands, a man had cleared a piece of land, it would be only in very exceptional circumstances that he would be disturbed, and on his death it would pass to his heirs eventually. The rights of ownership are more marked on the heavier cotton-growing lands. "The rest" are tribes living on the eastern and western flanks of the centre of the province, of no great importance, and in some cases merely survivals which cling to their tribal identity.

Observations on Indian Annelida.—In the *Proceedings* of the Seventeenth Indian Science Congress, held at Allahabad (Calcutta: Asiatic Society of Bengal), abstracts of fifty-three zoological communications are given. The majority of the papers were on parasites, insects, fishes, and cytology. It is interesting to note that several post-larval *Polygordius*, probably allied to *P. lacteus*, were taken in the tow-net near Madras, and with them, early larvæ. The latter were kept under observation for a few days and proved to have an 'amnion', as in *P. lacteus*. Another paper dealt with the alimentary glands in a surface-feeding earthworm, *Eutyphœus*. These glands, formerly mistaken for calciferous glands, are not situated on the œsophagus but much farther back—a little behind the middle of the body. They occur in connexion with the typhlosole, open into the gut by several apertures, and have a special blood supply. Preliminary experiments appear to indicate that they have a digestive (peptic) function.

Ascidians of Porto Rico and the Virgin Islands.—In connexion with the "Scientific Survey of Porto Rico and the Virgin Islands", Dr. Willard G. Van Name has, in vol. 10, part 4 (New York Academy of Sciences; 2 dollars), described the Ascidian fauna of the region. A very clear account of the 35 species collected from the coasts of these islands is given, with the diagnostic characters of the families and genera concerned. Numerous plates and sketches are used in illustration. The ascidians of Porto Rico and the Virgin Islands are, as might be expected, typical tropical and subtropical forms, some of which are restricted to the region including the West Indies, Gulf of Mexico, Caribbean, and Bermuda, whilst others, such as *Trididemnum savignii* and *Styela partita*, are found in practically all the warmer seas of the globe. A close relationship exists between the ascidian fauna of the West and East Indies, 18 of the West Indian species being represented in the East Indian region. One West Indian species, *Perophora viridis* (Verrill), is considered identical with *P. listeri* (Forbes and Hanley) of European waters. Two species only, *Ascidiella styeloides* and *Microcosmus anchyloderus*, are restricted to Porto Rico and the Virgin Islands. It is interesting to note that the ascidians of these islands, with one exception—*Pyura antillarum* (from 496 fathoms), are littoral forms. A considerable amount of dredging has yielded no truly deep-sea forms. Hartmeyer's revised classification of the Tunicata (1915) is used throughout, except that Lahille's orders—Aplousobranchiata, Phlebobranchiata, and Stolidobranchiata—are substituted for the Krikobranchia, Dictyobranchia, and Ptychobranchia of Seeliger. In addition, the distinct genus *Perophora* of Hartmeyer is included under the Ascidiidæ. The Botryllidæ are regarded as a distinct family of the order Stolidobranchiata. Linde (1923) and Michaelsen (1928) include them as a subfamily of the family Styelidæ, to the compound forms of which they are, without doubt, closely related.

Digestion of Cellulose by Insects.—Although a very large group of insects feed on woody tissues of plants and even on dry wood consisting almost entirely of cellulose, practically nothing is known as to whether these insects are able to digest cellulose. The problem

has been investigated successfully only with regard to wood eating termites, in which the digestion of cellulose was found by Cleveland to depend on the presence, in their intestinal tract, of symbiotic Protozoa (Flagellates) Many other wood-feeding insects were investigated by Buchner and his pupils from a purely anatomical point of view, and in the majority of them various symbiotic micro organisms, often harboured in special organs (for example, the so called 'fermentation chambers'), were discovered This anatomical evidence was considered sufficient to postulate a theory that the micro organisms must assist their hosts in the digestion of cellulose, and this theory is commonly accepted However, recent investigations by W Ripper (*Zeit vergl Physiologie*, 13 Bd, 2 Heft, 1930), who used biochemical methods, throw considerable doubts on the assumed rôle of symbiotic micro organisms in wood eating insects This author has proved the presence of a cellulase (cellulose digesting enzyme) in the intestinal juice of several insects not possessing symbionts, which result suggests that the digestion of cellulose can occur without the assistance of symbionts On the other hand, no cellulase was found in the 'fermentation chambers' of other wood boring larvæ, although these organs are required by Buchner's theory to harbour cellulose digesting micro organisms Again, in the case of certain unspecialised wood borers, the percentage of cellulose in the wood consumed and in the excreta proved to be the same Thus some wood borers do not utilise any of the cellulose of their food, others can digest it without symbionts, while the organs harbouring symbionts may bear no relation to the digestion of cellulose It appears that further research on biochemical and physiological lines is necessary for the elucidation of this highly interesting and complicated problem

The Tetraploid Chinese Primrose—*Primula sinensis* has been a subject of genetic investigation for many years A recent paper by Mrs Sverdrup Sömme (*Jour Genetics*, vol 23, No 3), who formerly worked at the Merton Laboratory, is concerned with the genetics and cytology of the tetraploid form This has arisen at various times in different strains and the view is favoured that it results from a suspended mitosis in the fertilised egg It is a stouter plant, a cell giant, with 48 chromosomes, and is less fertile than the diploid In the first studies of this tetraploid, Gregory found certain factors duplicated and he assumed that in meiosis the chromosomes would mate in pairs derived from either parent Mrs Sömme, however, finds that the genetic behaviour is that which would be expected if random pairing takes place between any two of the four homologous chromosomes in each set The two hypotheses are tested as regards the factor (S) for heterostylism, Gg for green or red stigma, and other pairs of factors Plants of constitution S_2s_2 gave an F_2 ratio of 35 1, and a ratio of 5 1 in back crosses, strongly supporting the theory of random conjugation between the four chromosomes Only two of the genes studied show complete dominance when present in a single dose Three of the genes show linkages in the tetraploids, which correspond to the linkages in the diploid But crossing over can take place between any two of the four homologous chromosomes In diakinesis, some of the sets of four are seen to be arranged as quadrivalent chromosomes, but usually only one or two are present in each pollen mother cell In all the attempts to cross $2n$ and $4n$ plants, only three triploid (sterile) plants were obtained This extensive and accurate record of genetic experiment is concluded with a discussion of tetraploidy as a factor in evolution, in which the author justly argues that the multiple factors in wheat and other plants have probably arisen through polyploidy

Cambrian Arthropods—Two of the many remarkable fossils discovered by Walcott in the Middle Cambrian of British Columbia have been re-studied by G E Hutchinson (*Proc U S Nat Mus*, **78, art 11**, pp 1 24, pl 1, 1930) One of these, a crustacean named *Opabinia*, was placed by Walcott in the Anostraca, and this view of its position has been confirmed by later writers The most conspicuous feature of the head is a large cylindrical process in front which, in living forms, is developed from the fused internal or frontal appendages of the antennæ in the male In structure *Opabinia* agrees with living Anostraca in many respects, but differs in the smaller number of trunk segments, the larger number of appendage bearing segments, the presence of only one or two post pedigerous segments, and the absence of branchiæ and a caudal fork On account of these differences it is considered that *Opabinia* should be placed in a separate sub order of the Anostraca The presence of this genus in a marine deposit is of interest since the living Anostraca have a fresh-water habitat *Rochdalia*, from the Middle Coal Measures of Lancashire, is thought to be allied to *Opabinia*, and was apparently of fresh water habit The other genus studied by Hutchinson, *Aysheaia*, was regarded by Walcott as a polychæt annelid, but later authors have been impressed by its resemblance to the living Onychophora (*Peripatus*, etc), and further study confirms this view of its relationship Some differences in structure, however, support the opinion put forward by Hutchinson that the Onychophora should be divided into orders 1, Protonychophora, to include *Aysheaia*, 2, Euonychophora, to include the living forms The Cambrian genus is of interest as being marine, whereas the living representatives are terrestrial C E Resser (*Proc U S Nat Mus*, **76**, art 9, pp 1 18, pls 1 7, 1929) describes and figures some beautifully preserved specimens of phyllocarid crustacea from the Lower and Middle Cambrian of British Columbia, Pennsylvania, and Manchuria

Middle Ordovician in Central Norway—In Ottadal, central Norway, a remarkable rock known as 'serpentine conglomerate', and hitherto regarded as a picrite lava or a tuff agglomerate, has been found by P A Øyen and Iver Haugen to yield a rich though obscure fauna Some three thousand specimens have been placed in the hands of the Swedish State-geologist, Herman Hedström, who has just published a preliminary report (*Avhandl Norske Vidensk Akad*, 1930, No 10, 10 pp, 2 pls) The shells have been changed into iron carbonate and details are often lost, but enough remains to identify the fauna as corresponding with the *Orthoceras* Limestone and *Asaphus expansus* beds of Sweden—the 3 c γ and β of Norway Gastropods abound, trilobites and cephalopods are fairly common, and there are also brachiopods and lamellibranchs Hedström regards the rock as a true conglomerate, contemporaneous with the fauna and formed from older peridotites In any case, this discovery will have to be reckoned with, in interpreting the geology of central Norway

Datum Planes for Charts—The problem of satisfactory datum planes for maps, and particularly hydrographic charts, is fully discussed by Mr H A Marmer in "Chart Datums" (U S Coast and Geodetic Survey, Special Publication 170) The arbitrary datum level is clearly of little value for charts, since it gives no absolute information regarding depths Moreover, it is clear that the datum plane should be one that is capable of recovery even if all bench marks are lost Tidal datum planes alone are satis-

factory A high-water datum may be very useful for certain purposes such as the clearance of bridges or warehouse construction along the water front, but it is unsatisfactory for nautical charts, inasmuch as it gives a false idea of security Mean sea level datums are fairly satisfactory but may cause trouble or danger in shoal areas The needs of the sailor are best served by low water datum planes, but the de termination of these is not an easy matter, owing to periodic variations in the tide Mr Mariner discusses the nature and extent of these variations A mean low water datum is relatively easily determinable on any coast and may be fairly satisfactory It is used on the charts covering the Atlantic coasts of the United States A datum of lower low water is reached from half as many observations as that of mean low water This is most suitable for coasts on which the tide is of the daily and not of the semi daily type It is used on the Pacific coast charts of the United States Another datum that can be used is that of spring low water This, of course, requires a long time for determination, and tends, in use, to give an appearance of unnavigability to many waters, and also to indicate rocks and reefs which are rarely visible to the mariner

Recent Researches on Relativity —Lemaitre and Sir Arthur Eddington have shown that our actual universe may probably be considered as expanding from an initial state something like Einstein's world filled with matter, towards a limiting state like de Sitter's world ', which is empty or rather has all the matter swept into unobserved corners It has been suggested that the concentration of matter, originally uniformly distributed, into local condensations may have started this expansion To test this hypothesis, W H McCrea and G C McVittie (in *Monthly Notices Roy Ast Soc*, Nov 1930) study non stationary uni verses where there is a single condensation of matter at the origin This is proved to lead not to an expan sion as anticipated, but to a contraction Dr G C McVittie also contributes (*Proceedings* of the Edin burgh Mathematical Society, ser 2, vol 2, part 3 Jan 1931) a comparison between the general relativity theory and Einstein s newer unified field theory It is shown that the latter, applied to the problem of a particularly simple type of field with axial symmetry, gives results which do not appear to correspond to physical facts The conclusion can scarcely be evaded that Einstein's latest theory, at any rate in the form at present published, contains serious defects

Artificial Disintegration by α-Particles — The paper by J Chadwick, J E R Constable, and E C Pollard in the February number of the *Proceedings of the Royal Society*, in which they describe their new experiments on the disintegration of the nuclei of light elements by α particles and discuss these and the recent experi ments of Bothe and Fränz and of Pose, although leaving much detail still to be supplied, marks a definite advance in knowledge of the properties of nuclei The assumptions needed to explain such facts as are known at present are few and simple the nuclei are supposed to have definite levels for protons and α particles, to be composed of these and elec trons, the number of the α particles being as large as possible, all the α particles of a stable nucleus are supposed to be in the same energy level, but not more than two protons can be put into the same proton level Two main types of disintegration are supposed possible, in one of which the α particle is captured by the nucleus—as appeared to be so in the cases of the disintegration of nitrogen photographed by Blackett—and in the other, the proton is ejected without capture of the α particle The evidence for the latter type is rather unsatisfactory, but it is of particular importance, since the continuous distri bution of energies amongst the protons produced in this way could give immediately the level of the proton in the nucleus, disintegration with capture of the incident particle gives a line spectrum ' of velocities for the protons The changes in energy in volved in the disintegration, which can be calculated from these experiments, also extend Aston s measure ments of the mass defects of nuclei with the mass spectrograph, and in some cases furnish an inde pendent check on these, although most of the nuclei formed in the disintegrations have not been studied with positive rays, and many are indeed rare It is mentioned that the production of γ rays from light elements by α particle bombardment which was recently reported by Bothe and Becker (see NATURE, Feb 21, p 288), has also been detected by H C Webster in the Cavendish Laboratory

Solubilities in Hydrogen Fluoride —A comparison of the solvent properties of liquid hydrogen fluoride and of water with respect to salts is possible from some results with the first solvent, which are com municated in the January number of the *Journal of the American Chemical Society* by Bond and Williams The solubility of lithium hydrogen fluoride was measured between 0° and 40° Zinc, magnesium, and calcium fluorides were found to be very insoluble, chromium fluoride is quite soluble, potassium iodide reacts with hydrofluoric acid There is a fair similarity in the solvent action of water and hydrofluoric acid with the salts used A determination of the critical tem perature of hydrogen fluoride, made with a special apparatus, gave 230 2°

Conductivity of Electrolytes in Nitromethane and Nitrobenzene —The *Journal of the Chemical Society* for January contains two papers by Sir H Hartley, Murray Rust Hadow and Wright on the conductivi ties of some salts in nitromethane and nitrobenzene In the case of nitromethane only tetraethylammonium salts gave a linear relation between equivalent con ductivity and $\sqrt{c}$, and these also show good agree ment with the Debye Huckel Onsager equation All the other salts show large divergences from ideal behaviour Some of them are weak electrolytes in nitromethane, although they all behave as strong electrolytes in methyl and ethyl alcohols Since the dielectric constant of nitromethane is greater than those of the alcohols, the results show that ionic association is not entirely controlled by the electrical forces between the ions Perchloric acid is a fairly strong acid in nitromethane and the mobility of the hydrogen ion is 63 Thus this ion has not the abnormally high mobility in nitromethane which it possesses in hydroxylic solvents Other acids appeared to be very weak in nitromethane In nitrobenzene, tetraethylammonium picrate and perchlorate are strong electrolytes, and the results are in agreement with those calculated from the Debye Huckel Onsager equation, but silver perchlorate is appreciably associ ated Perchloric acid is an electrolyte of intermediate strength, and the mobility of the hydrogen ion is 43, which shows that it is not abnormal, as in hydroxylic solvents Hydrogen chloride, benzene sulphonic acid, and benzoic acid are very weak electrolytes Nitro benzene is similar to nitromethane as an ionising solvent, but the tendency towards ionic association is rather greater in the former The dielectric constants are 35 and 37 respectively

Resolution of *dl*-Menthol —NATURE, Mar 14, p 421 Last line but two of paragraph For ' *d* menthol" read '*l*-menthyl *d*-camphor 10 sulphonate"

Milk Tests in Lanarkshire Schools *

THE Department of Health for Scotland has recently issued a report on the investigation into the effect of the addition of milk to the diet of school children The data have been compiled and annotated by Dr Gerald Leighton, Medical Officer (Foods), and Dr Peter L McKinlay, Medical Officer (Statistics)

Twenty thousand children were concerned in the experiment, 10,000 being given a daily ration of milk and a like number being used as control subjects All the milk used was Grade *A* (Tuberculin Tested) Half of the milk was given in the raw state and half was pasteurised

The schools selected for the tests were all situated in the densely populated industrial part of the county While no account was taken of the distress prevalent in these localities in the selection, it has been estimated that one third of the children came from homes in which there was unemployment, complete or partial The ages of the subjects ranged from five years to twelve years The sexes were balanced in each age group

The teachers showed great interest in the experiment, and their "remarks" on the various subjects are often enlightening One teacher noticed that "in the playground buoyancy and pugnacity developed to an alarming extent" Another states that a little girl increased in vitality to such an extent that she boasted to her teacher of her ability to fight her big brother

While the physical benefits of the experiment made themselves fairly obvious, it was not easy to estimate the mental improvement However, many teachers have reported great improvements in mental alertness, especially among the younger children Others say that some of the children became drowsy One boy, who hitherto was very backward in reading, improved greatly and became very smart in reading, arithmetic, and history Another child, formerly very morose and sullen, has become bright and talkative

There are complete records of the progress of 17,159 children These records are in three parts—(*a*) Controls, (*b*) children fed with raw milk, (*c*) children fed with pasteurised milk These are further subdivided according to age and sex

Tables were prepared in such a way that not only the average increase in height or weight for the whole group, but also the average increase in height or weight for children of a given initial height or weight could be calculated In view of the fact that there were definite differences of weights and heights in the controls compared with 'feeders' at the beginning of the experiment, it was considered advisable to inquire whether the amount of growth within this period was affected to any appreciable extent by original physique that is, whether the heavier or taller child added more or less to its height or weight than the lighter or shorter child For this purpose coefficients of correlation between original weight and original height and change in height were calculated for the control group From these results it was inferred that there was no uniform tendency for gain in weight or height to be influenced by original weight or height

The conclusions may be summarised as follows

(1) The addition of milk to the diet of school children is reflected in a definite increase in the rate of growth, both in weight and height

(2) There is no obvious or constant difference in this respect between the sexes There is little evidence of definite relation between the age of the children and the amount of improvement The results do not support the popular belief that the younger children derived more benefit than the older children As manifested merely by growth in weight or height, the increase found in younger children through the addition of milk to the usual diet is certainly not greater than, and is probably not even so great as, that found in older children

INCREASE IN WEIGHTS (IN OUNCES) IN THE THREE GROUPS

Age	Boys			Girls		
	Control	Raw Milk	Pasteurised Milk.	Control	Raw Milk	Pasteurised Milk.
5	11 64	14 88	15 65	7 00	14 50	6 62
6	13 75	13 51	9 96	11 21	10 61	10 05
7	11 17	14 85	15 55	8 90	11 22	12 94
8	11 38	14 21	15 21	9 77	13 40	13 37
9	9 53	13 43	11 83	7 87	13 81	12 52
10	7 10	13 53	10 39	9 51	15 08	18 96
11	6 14	12 74	11 05	12 62	24 92	17 08

INCREASE IN HEIGHTS (IN INCHES) IN THE THREE GROUPS

Age	Boys			Girls		
	Control	Raw Milk	Pasteurised Milk	Control	Raw Milk	Pasteurised Milk
5	0 75	0 95	0 94	0 86	0 64	0 87
6	0 80	0·87	0 87	0 80	0 86	0 84
7	0 76	0 87	0 82	0 75	0 84	0 81
8	0 74	0 82	0 79	0 71	0 81	0 78
9	0 69	0 80	0 74	0 66	0 76	0 78
10	0 68	0 76	0 68	0 71	0 79	0 72
11	0 69	0 74	0 70	0 77	0 86	0 81

(3) In so far as the conditions of this investigation are concerned, the effects of raw and pasteurised milk on growth in weight and height are, so far as can be judged from this experiment, equal

Dr J P Kinloch, Chief Medical Officer of the Department of Health for Scotland, says, in a prefatory note, that the scheme was made possible by a grant of £5000 from the Empire Marketing Board, which approved its purpose and the selection of Lanarkshire for the experiment The Distress in Mining Areas (Scotland) Fund financed the experiment also, by a grant of £2000 Individuals and firms interested in the dairying industry contributed £477 The results, states Dr Kinloch, demonstrate that the addition of milk to the children's diet results in improved physique and mental alertness They also suggest that, apart from its own food value, milk enables the other constituents of the ordinary diet to be fully utilised as growth factors

It is significant that, by powers conferred by the Education (Scotland) Act, 1930, local authorities may make a ration of milk available for school children The exercise of these powers would, Dr Kinloch states, affect 800,000 children in Scotland, and, by improving their physical and mental well-being, would have a powerful influence in improving the quality of the Scottish race

Modern Metal Cleaning

THE increasing use of electroplating processes for the protection from corrosion, the reduction of wear, the building up of worn parts, or the actual manufacture of components, coupled with the fact that the production of an adherent metal coating depends on the complete removal of all foreign matter from the basis metal, makes an account of the means whereby this clean surface may be obtained by mass production methods one of considerable importance A paper on the subject was presented by Messrs L Wright and F Taylor to the Electroplaters and Depositors' Society recently

Cleaning tanks of steel, iron, or wood, with or without electrical connexions, still remain the most common means of achieving this end, and large volumes of cleaning solution, at a steady temperature, are required if the dirt is not to be redeposited on the work Such tanks may be heated by gas or by electrical immersion heaters, but a steam coil, placed at that side of the tank opposite the overflow dam, is the best This causes the solution to boil towards the dam, carrying with it surface scum or oil The coil should be shielded with perforated sheet metal, and the solution, gushing through the holes, effects adequate agitation For the general run of cleaning, the solution should be maintained at the boiling point, which has the incidental advantage that as the metal expands the dirt is loosened

Agitation by compressed air has the disadvantage that it rapidly cools the solution and promotes foaming In the absence of steam heating, the most convenient method for rapid and efficient cleaning is by an arrangement of paddles

Electric cleaning, which is rapidly coming into general use, adds a mechanical to the chemical effect The passage of the direct current though the solution liberates hydrogen in small bubbles at the cathode, forces the particles of dirt away from the metal, and carries them into the bulk of the solution, where they are readily emulsified and suspended The potential across the tank should be of the order of 6 volts, and the cathode current density 30 40 amp per sq ft Any danger of metals such as tin, lead, or zinc accumulating on the cathode may be eliminated after the cleaning by temporarily making the article the anode, this removes any such adherent film The accumulation of colloidal hydroxides can be avoided by the occasional use of supplementary steel electrodes, on which the colloidal hydroxides adhere The electrodes are from time to time removed from the bath and the accumulations scoured off

Effective rinsing after cleaning, in clean, soft water, is as important as the cleaning itself, as it washes away the dirt which the cleansing solution has loosened and softened Hard water reacts with the soap films forming a calcium soap, which adheres to the work The use of two tanks is recommended, the first hot and the second cold, and after rinsing, the article should be chemically clean, as shown by the surface being uniformly wetted

Meteorology in India *

THE year 1929–30 was one of exceptional expansion and reorganisation in the Meteorological Department of the Government of India, arising from the formation of new air-routes To meet the meteorological requirements of such air routes, and of additional contemplated air routes not yet in operation, as laid down in various international recommendations, it was found necessary to arrange for the preparation, twice daily, of weather charts at regional forecast centres, and to raise the status of most of the third class weather stations to second class status A new forecast centre in charge of a fully qualified meteorologist had to be opened at Delhi in November 1929 in order to supply weather forecasts to the State Air Mail and other aviators flying on the Jodhpur Delhi and Delhi Allahabad air routes, while the existing forecast centre at Karachi made itself responsible for forecasts for the Karachi Jodhpur route Further expansion was necessitated by the imminence of additional air routes from Delhi to Calcutta and Calcutta to Rangoon, and detailed proposals for meeting this need were submitted to the India Government

One of the most urgent needs of aviators is knowledge of the winds to be expected at various altitudes, in order that flying may be done with the maximum of wind assistance This has necessitated an increase of stations equipped for making observations of upper wind by means of pilot balloons, an increase which has reacted upon the organisation of the Upper Air Observatory at Agra, where the plant for producing the hydrogen required for the balloons is situated, an increase both of the plant and of the staff of that observatory has therefore become essential

All this activity on the side of organisation and equipment has not prevented useful research work from being done Many subjects have received especial attention, among which may be noted that of the electrical charge of thunder-clouds, which has resulted in observational support being found for Simpson's breaking drop theory Microseisms caused by earth tremors due to ocean waves have been studied in relation to the storms on the seas around India, and interesting relationships have been obtained, while the Upper Air Observatory at Agra has made a special study of the 'nor'-westers' that occur in Bengal in spring and early summer, a special expedition being organised in 1929 for this purpose These brief notes indicate only a few of the activities of a meteorological service that is rapidly pushing its way into the forefront of investigational enterprise

University and Educational Intelligence.

CAMBRIDGE —The Natural Sciences Tripos Committee has issued a report to the University and has made the following recommendations, to take effect after the examination to be held in 1933 (1) the examination in mathematics in Part I of the Natural Sciences Tripos shall be conducted by two special papers instead of by means of the papers set in Part I of the Mathematical Tripos The total maximum of marks allotted to mathematics shall be half that assigned to each of the other subjects, (2) all candidates for Part I of the Tripos shall be required to offer not less than three subjects exclusive of mathematics, (3) the subject mineralogy in Part I of the Tripos shall be redefined to include both crystallography and petrology It is also recommended that the written examination in mineralogy consist of two papers (1) the elements of crystallography, crystal optics, and descriptive mineralogy, (2) (a) crystallography and crystal physics, (b) crystal structure and crystal chemistry, (c) mineralogy and ore deposits, (d) petrology Two of these sections only are to be taken, with the restriction that (d) shall be taken only by students who offer also the subject of geology This report will be discussed next term

In NATURE of Mar 14, p 424, it was stated that Dr J Wishart had been appointed University lecturer

in statistics This is incorrect Dr Wishart has been appointed to the readership in statistics, to succeed Mr G Udny Yule Mr Udny Yule, formerly lecturer in statistics, was appointed reader on Jan 1 last, but he will vacate this post at the end of the present academical year A lecturer in statistics is to be appointed by the Faculty of Economics

EDINBURGH —The Senatus Academicus of the University has resolved to confer the honorary degree of Doctor of Laws, at the graduation ceremonial on July 2, on the following among others Dr E J Allen, Director of the Marine Biological Laboratory, Plymouth, Sir George Berry, M P for the Scottish Universities, formerly lecturer in opthalmology in the University of Edinburgh, Sir Walter Morley Fletcher, Secretary of the Medical Research Council

OXFORD —Congregation has accepted with thanks a gift of £200 from Mrs Clara Brooks in memory of her son, Clement C Brooks, formerly on the staff of the Imperial Forestry Institute, who was killed in a bicycle accident The interest of this sum is to be devoted to the purchase of entomological books and apparatus for the use of the Forestry Department

APPLICATIONS are invited by the Salters' Institute of Industrial Chemistry for a limited number of fellowships for chemists of post graduate standing The fellowships are each of the value of from £250 to £300 and their object is to afford additional and special training, at home or abroad, preparatory to a career in industrial chemistry The Institute is also offering a limited number of grants in aid to young men and women employed in chemical works in or near London, of 17 years of age and upwards, who desire to extend their education for a career in chemical industry Applications, in each case, should be made by May 1 at latest to the Director of the Institute, Salters' Hall, St Swithin's Lane, E C 4

THE March issue of the *School Science Review* devotes sixty pages to reports of the proceedings of the Science Masters' Association at the Birmingham meeting held early in January (see also NATURE, Jan 17, p 111) The presidential address by Sir Charles Grant Robertson, vice chancellor of the University of Birmingham, pleads the claims of biology to general recognition as an essential constituent in the school science curriculum The general principles of science cannot be imparted by instruction limited to physics, chemistry, and mathematics, and the omission of biology is stigmatised as a crime against science Sir Charles invited the Association to ask the Royal Society to appoint a small but representative committee to attack the problem of where, when, and in what system of allocation the teaching of science ought to begin and be carried on alike in the schools and the universities In a discussion on science education of the boy up to eighteen, Prof F W Burstall, vice principal of the University, pointed out that in competition with the other sciences, biology inevitably suffers from the handicap that it is generally believed to be not so likely to help a boy to earn a living when he leaves school A discussion on the subject of 'general science' disclosed a remarkable consensus of opinion in favour of the teaching of some biology to all pupils as an element of 'general' science, and an interesting description was given of a course arranged at Harrow as an introduction to science, occupying five periods weekly during one term Prof A W Nash, professor of petroleum technology in the University, addressed the Association on the work of the physicist and chemist in the petroleum industry, and the Bishop of Birmingham gave a lecture on "A Finite Universe?" The *Review* gives reports of both addresses

Birthdays and Research Centres.

Mar 22, 1868 —Prof A FOWLER, F R S, Yarrow research professor of the Royal Society and professor of astrophysics in the University of London, Imperial College of Science, South Kensington

In view of the considerable number of research students, an attempt is made to cover a wide field of spectroscopic research Continued attention is being given to the spectra of elements at successive stages of ionisation, and to the production and analysis of band spectra Some progress has also been made towards the establishment of standard wave lengths in the ultra violet and Schumann regions of the spectrum New work contemplated is the investigation of problems involving intensities and contours of spectral lines, and work on hyperfine structure, for which equipment has recently been provided

At present I am specially occupied with an investigation of the spectra of flames, in the belief that our present knowledge as to the molecular origins of numerous bands will throw considerable light on some of the processes of combustion

Mar 22, 1868 —Prof ROBERT A MILLIKAN, chairman of the Executive Council of the California Institute of Technology and director of the Norman Bridge Laboratory

I am still pursuing quite intensively my studies in the field of the cosmic radiations, for they have relations to meteorology not yet fully explored and their values at very high altitudes still have something to teach us about the precise nature of the cosmic atom building processes Also, as an adjunct to these studies, I am interested in the problem of the origin of the very heavy elements and, as a possible clue to its solution, am collecting further data, by a new method, on the terrestrial distribution of the radioactive elements Artificially stimulated radiations of high penetrating power are also a part of the programme

Mar 25, 1863 —Dr SIMON FLEXNER, For Mem R S, director of The Rockefeller Institute for Medical Research

The constantly growing number of those diseases of man, the lower animals, and plants, shown to be brought about by filterable agents or viruses, emphasises their known significance Among human beings, a disease of this character is poliomyelitis or infantile paralysis The modes of infection and of extension of the virus of this disease are questions of outstanding importance Ever since 1909, when the first serial transmission of the disease to monkeys was accomplished (Flexner and Lewis), these questions have commanded attention The indications, then secured and since confirmed, are to the effect that the virus is nerve conducted, as it enters and even as it leaves the body of infected human beings and animals via the respiratory mucous membranes

Not only is this finding of importance in so serious a disease as poliomyelitis, but corresponding questions are of high interest in connexion with virus diseases generally, as is also the question of the precise nature (chemical or otherwise) of the viruses themselves

Mar 27, 1855 —Sir J ALFRED EWING, K.C B., F R S, formerly principal and vice chancellor, University of Edinburgh, previously director of naval education and professor of mechanism and applied mechanics, University of Cambridge.

I am too old now for individual research But a long experience of laboratories and of administration

can still be turned to account in committee work of the kind that is increasingly done under such official bodies as the Department of Scientific and Industrial Research

I have learnt to value committees as instruments of research Often they achieve results which would otherwise be out of reach It has been said of them that they keep minutes and waste hours The jibe would be pointless if it did not contain a half truth But in fact, when sensible men serve on a committee, not much time is wasted One finds that in some kinds of research, especially in the application of science to industry, the directing is best done by a committee

In a committee, an old member, particularly when he happens to be in the chair can do much to check waste of time His very age becomes a useful asset It has developed his historical sense, it gives him a sort of authority He will focus attention on essentials He will explore the minds of his colleagues, collect their ideas, induce each to contribute and finally lead them to discover, perhaps to their surprise, that they are in agreement A committee is a fluid holding potential wisdom in solution, from which conclusions are to be crystallised out The process should not be hurried, but if, in the long run, a report issues which has some of the definiteness of a crystal, the time of the committee will not have been misspent

Societies and Academies

LONDON

Royal Society, Mar 12 – **E W Fish** On the reaction of the dental pulp to peripheral injury of the dentine A series of earlier experiments in which diffusible dyes were placed in the pulps of human teeth indicated that when primary dentine is injured at the periphery either by caries or attrition, the whole tract of affected tubules dies and becomes walled off from the pulp by secondary dentine The nature of the reaction is found to vary with the severity of the lesion The usual result is that the pulp ends of the injured tubules are sealed off by a deposit of calcium salts, and this is followed by a deposit of secondary dentine —**E B R Prideaux** The combination curves hydrogen ion regulating power, and dissociation constants of gelatin The properties of gelatin as an ampholyte have been deduced from the combination curves, in which pH is expressed as a function of added acid or alkali Considerable differences were noted between the combination curve of gelatin and those of amino acids By means of equations which express the simultaneous relations (*a*) absence of inflection at the isoelectric point, (*b*) the existence of the iso electric condition, the constants of the basic and acidic dissociations have been calculated on the assumptions that gelatin consists mainly (i) of un dissociated molecules, (ii) of amphoteric ions at its isoelectric point On either theory, three constants are obtained, of which one acidic and one basic constant are nearly equal to one another —**R Snow** Experiments on growth and inhibition Since it had been found previously (*New Phytologist*, vol 28, p 345, 1929) that in older and taller pea seedlings the young leaves near the apex inhibit the axillary buds near the base of the stem more strongly than in very young short seedlings, experiments were carried out to test whether the increase in strength of inhibition is due to the greater length of intervening stem It is concluded that the strength of inhibition increases with increasing length of intervening stem Axillary buds normally grow to a certain length before they are stopped by inhibition, and they are susceptible to inhibition during their early growth as well as later The interpretation of the increase of inhibition is briefly discussed —**C H Lea** The effect of light on the oxidation of fats A quantitative iodimetric method for estimation of the peroxide oxygen present in rancid fats is described By this means it is possible to follow the atmospheric oxidation of pure fats or of animal fats in the tissue, and, in conjunction with a suitable source of light, to forecast the relative susceptibilities of fats to oxidation This method, with a quantitative modification of the Kreis test, has been used to investigate the effect on the oxidation of fats —**H Munro Fox** and **H Ramage** A spectro graphic analysis of animal tissues Tissues of annelids, molluscs man, and some other animals have been studied Iron and copper were present in all kinds of protoplasm investigated Manganese was widely distributed The manganese content of tissues varies with the locality in which a given species of animal lives Nickel and cobalt occurred spasmodically, the former being more frequent Except in one case, all high concentrations of nickel were accompanied by cobalt In one tissue only did cobalt occur without detectable nickel Lead and silver both exhibit an irregular distribution (see also NATURE, Nov 1, 1930 p 682) – **A S Parkes** The reproductive processes of certain mammals (1) *Cricetulus* failed to breed under laboratory conditions but it was found possible to investigate the cyclic changes occurring in the non pregnant females, about half of which possessed perfectly normal reproductive organs The cycle is very similar to that of the mouse Cornification of the vaginal epithelium, diagnosed in the live animal by examination of the vaginal contents, was found to be associated with the period of ovulation The average length of cycle was a little under five days and the average number of follicles maturing at one period of ovulation was eight —**F G Spear** The delayed lethal effect of radium on tissue cultures *in vitro* –comparison of continuous and spaced radiation It was found to be immaterial whether the radiation was given in one dose of six hours or in six fractional doses of 60 minutes each at 24 hourly intervals

LEEDS

Philosophical and Literary Society, Dec 9 – **G J Blakey** The parabolic developable of the trinodal cubic surface The following results are due to Prof A E Jolliffe and W P Milne ' There is a sextic envelope $I_6 \equiv J_6 \quad U_2 I_4 = 0$ (where J_6 and I_4 are respectively the harmonic and equiharmonic envelopes of the plane quartic curve, and U_2 is a conic), which touches the 24 inflexional tangents of the quartic, and the 12 bitangents of a Steinerian Complex The conic U_2 is a sextangent conic of J_6, and there are 63 such conics corresponding to the 63 Steinerian Complexes " Dr Blakey has carried out the analo gous investigations in the case of a trinodal cubic surface —**E C Stoner** The specific heat of electricity in ferromagnetics The theory of the specific heat of electricity based on the application of the Fermi Dirac statistics is inadequate as it leads to values incorrect in magnitude and sign A metal is treated as an equilibrium distribution of atoms, ions, and free electrons It is shown that the observed change in the specific heat of electricity at the Curie point in nickel is consistent with the ferromagnetic properties —**G W Brindley** On the damping of the torsional oscillations of a sphere in a viscous medium An expression is developed for the damping of the tor sional oscillations of a sphere in a viscous medium from which the viscosity of the medium may be obtained The expression has been tested for water, but the observed damping is found to be 5–10 per cent greater than the calculated value —**J Duffey**

The electric beam discharge in argon Electron beam phenomena at low pressures are described, and space-potential measurements obtained by use of a cold exploring electrode given Certain parts of the discharge can be explained on the ordinary space-charge theory --**J E Taylor** Experiments on the efficiency of an electron gun An improved type of electron gun is described in which better focusing and higher beam efficiency are obtained by interposing between the emitting filament and gun muzzle a negative screen with a small central hole This screen has low negative potentials applied to it, and curves are given which show that maximum efficiency is attained at a certain screen potential which varies with the gas pressure The device resembles in its action the soft three electrode valve --**H M Dawson and E Spivey** The determination of catalytic co efficients from iso catalytic data Values for the coefficients which measure the catalytic activity of the non ionised acid (k_m) and the acid anion (k_a) may be derived from the minimum reaction velocities (iso catalytic velocities) which are observed when acetate buffers of the type $c\ CH_3CO_2H + x\ CH_3CO_2Na$, in which c is constant and x variable, are employed as catalysts for the reaction between acetone and iodine The experimental data for series of solutions with $c = 0\ 02$, $0\ 1$, and $0\ 5$ respectively and a 0 75 molar solution of sodium chloride as the reaction lead to values of $k_m = 1\ 3 \times 10^{-6}$ and $k_a = 3\ 3 \times 10^{-6}$ for the undissociated acid and the acetate ion (Temperature, 25°, acetone concentration, 20 c c per litre)--**J W Belton** The activity coefficient of a non electrolyte in aqueous salt solutions from solubility measurements Measurements of the solubility of *N* chloroacetanilide in aqueous solutions of sodium chloride, barium chloride, and magnesium sulphate show that the quantity of the anilide dissolved by 1000 grams of water is an exponential function of the ionic strength (μ) for each of these electrolytes up to $\mu = 4$ —**J Grainger and Edith Angood** The insect transmission of raspberry mosaic The mosaic disease of raspberries has been shown to have an insect vector in a species of aphid—*Aphis rubiphila* The mottling associated with the mosaic disease was induced in unmottled plants by caging aphids, transferred from a diseased cane, on the wild plants Untreated controls remained healthy, so the insect is deemed to be the transmitter - **R D Preston** The structure of the wall of *Valonia ventricosa* Recent X ray work has shown that the cellulose wall of the plant is built up of repetitions of anhydro glucose residues in a space lattice This lattice has a definite orientation with reference to the surface of the wall, but the data leave open the orientation of the anhydro glucose chains in the tangential plane As a result of investigations with the polarising microscope the wall of *Valonia ventricosa* is seen to consist of a mosaic of small areas, each with its own chain direction

PARIS

Academy of Sciences, Feb 2 —**V Grignard and L Lapayre** The β enynes and β diynes A study of the influence on an intermediate CH_2 group of two triple bonds or one double and one triple bond The hydro carbons $(C_6H_5)C\ C\ CH_2\ C\ C(C_6H_5)$, $(C_4H_9)\ C\ C\ CH_2\ CH\ CH_2$, and $(C_5H_{11})\ C\ C\ CH_2\ CH\ CH_2$ have been prepared and the acidity of the central CH_2 group examined by three methods, treatment with sodium, heating with sodium amide, and allowing to react with alkyl magnesium compounds —**Edmond Sergent A Donatien, L Parot, and F Lestoquard** The mode of transmission of North African bovine theilerosis by the tic *Hyalomma mauritanicum* The larva nymphs of *H mauritanicum* are infected by cattle carriers of *Theileria dispar* and, in the adult state, contaminate fresh cattle The *Theileria dispar* infection is not hereditary in the tic —Émile Cotton was elected *correspondant* for the section of geometry, and Sentiro Ikeno *correspondant* for the section of botany —**Chevalley** The relation between the number of classes of a sub body and that of a super body —**Paul Lévy** The maximum gain in the course of a game of heads and tails —**P Vincensini** A characteristic property of spiral surfaces —**J Doubnoff** The tensorial characteristics of certain classes of surfaces and of their networks —**V Lalan** The covariant derivatives of tensors —**V Romanovsky** The zeros of stocastic matrices —**Georges Valiron** A general property of meromorph functions —**Basile Demtchenko** Some bidimensional applications of the cavitational theory of Riabouchinsky —**Edgar Pierre Tawil** The electricity set free in quartz crystals by bending Detailed account of experiments on the electrical effects produced by bending quartz cylinders The results appear to be in contradiction with the conditions of symmetry of the crystal and with the laws of piezo electricity —**Benjamin Jekhowsky** A new expression of the *j* orientation of the great circle of asteroids —**R de Mallemann and P Gabiano** The magnetic rotatory power of the halogen derivatives of the saturated hydrocarbons in the gaseous state The figures given, together with those previously published, permit the approximate calculation of the atomic magnetic rotatory powers of hydrogen, carbon, chlorine, bromine, and iodine The rotatory powers of the ions in aqueous solutions are much greater than those of the corresponding atoms For the three halogen elements, however, the ratio of the Verdet constants is the same, about 3 2 —**Er Toporescu** The variation in the colour of cobalt chloride solutions At laboratory temperature, cobalt chloride in solution in methyl alcohol is rose violet, but in ethyl, *n* propyl, *n* butyl, and amyl alcohols it is an intense blue On lowering the temperature the colour changes from blue to pink in each case It is concluded that the change of colour of the solutions is a function of the dielectric constant and is caused by a change in the molecular condition of the solvent —**Mlle Suzanne Veil and L Bull** The microscopic and cinematographic study of Liesegang rings —**A Travers and Schnoutka** The separation of beryllium and aluminium A modification of Berthier's method, based on the precipitation of alumina with alkaline bisulphite —**M Tiffeneau and Mlle Jeanne Lévy** The benzoin condensation The influence of the nature of the radicals on the formation of mixed benzoins —**C Gaudefroy** New applications of an apparatus for measuring the angle of the optic axes —**Roger Heim** The phyletic connexions between the ochrospore Agarics and certain Gasteromycetes —**Maurice Hocquette** The influence of the substances secreted by the radicles in the course of formation on the nucleus of the neighbouring cortical cells —**O Munerati** Competition between *Ustilago Tritici* and *Tilletia Tritici* in the same wheat plant —**Mlle M L Verrier** The sensorial organs of some deep sea fish The results of the examination of a dozen specimens collected at depths of 2900 3000 metres It is difficult to find in these fishes a relation between the morphology of the sense organs and what is known of their mode of life and their habitat —**Raymond Hamet** 3 4-Dioxyephedrin and 3 4 dioxynorephedrin —**Tchang-Li** A new case of embryogenic condensation in a nudibranch (*Doridopsis limbata*) —**L Doljanski, J J Trillat, P Lecomte du Noüy, and An Rogozinski** The action of X-rays on tissue cultures *in vitro* The results of the experiments

prove conclusively that the idea of an exceptional resistance of cells cultivated *in vitro* is unfounded — Léon Velluz and Jean Loisleur The properties of proteocellulosic membranes —R Vladesco, D Simci, and M Popesco A new function of the stomach The rôle of this organ in the metabolism of urea — C Levaditi, P Ravaut, P Lépine, and Mlle R Schœn The presence of a virus pathogenic for the ape in certain venereal buboes of man

Diary of Societies.

FRIDAY, MARCH 20

ASSOCIATION OF ECONOMIC BIOLOGISTS (in Botany Lecture Room, Imperial College of Science and Technology), at 2 30 —Dr A C Thaysen Retrospects and Prospects of the Economic Application of Microbiology —H J Bunker A General Review of the Microbiology of Cellulose and its Associated Compounds.

ROYAL SOCIETY OF MEDICINE (Balneology and Climatology Section), at 5.—Dr W Edgecombe and others Discussion on Osteoarthritis

LONDON SOCIETY (at Royal Society of Arts), at 5 —Lord Moynihan Ancient Methods of Surgery

PHYSICAL SOCIETY (at Imperial College of Science) (Annual General Meeting), at 5 —Presentation of Duddell Medal, 1930, to Sir J Ambrose Fleming

ROYAL SANITARY INSTITUTE (at Technical College, Lincoln), at 5 —L O Need and others Discussion on Houseboats on Inland Waterways —S C Baggott and others Discussion on Refuse Collection and Disposal

ROYAL COLLEGE OF SURGEONS OF ENGLAND at 5 —Sir Arthur Keith Demonstration of the Anatomy and Nerve Supply of the Diaphragm.

INSTITUTION OF MECHANICAL ENGINEERS at 6 —R S. Allen and W E. W Millington Modern Methods of raising Water from Underground Sources

NORTH EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (at Mining Institute, Newcastle upon Tyne), at 6.—T Millican Corrosion with Reference to Boilers

INSTITUTION OF ELECTRICAL ENGINEERS (Meter and Instrument Section) (Informal Meeting), at 6 30 —W Lawson and others Discussion on Should the Bottom Bearings of Meters be Oiled?—W Holmes and others Discussion on Are Cobalt Steel Magnets Desirable for Use as Permanent Magnets for Instruments?—Lt. Col K Edgcumbe and F Hope Jones Discussion on Are Synchronous Motors or Clocks More Suitable for Time Service?—J W Record and W Phillips Discussion on Are Long Scales Preferable to Short in Indicating Instruments?

SOCIETY OF DYERS AND COLOURISTS (London Section) (at Dyers Hall E C) at 6 45 —Capt Whiteman Spray Dyeing

INSTITUTE OF CHEMISTRY (Manchester Section) (Annual General Meeting) (at 'Manchester Ltd , Manchester) at 7 —Prof R. M Caven Lecture.

INSTITUTION OF MECHANICAL ENGINEERS (jointly with Institution of Automobile Engineers) (at Merchant Venturers Technical College Bristol) at 7 —Dr I S. Davies An Experimental Investigation into Induction Conditions, Distribution and Turbulence in Petrol Engines.

SOCIETY OF CHEMICAL INDUSTRY (Newcastle Section) (at Armstrong College Newcastle upon Tyne), at 7 30 —H W Howes Pyrex Glasses their Properties and Uses

JUNIOR INSTITUTION OF ENGINEERS, at 7 30 —W S Roberts Some Token Systems of Railway Signalling

ROYAL SOCIETY OF MEDICINE (Electro Therapeutics Section), at 8 30 —Dr Chalmers Watson Radiation in Relation to Human and Animal Life

ROYAL INSTITUTION OF GREAT BRITAIN, at 9 —Prof E N da C Andrade Sound Sand and Smoke New Light on Old Problems

GEOLOGISTS ASSOCIATION (North East Lancashire Group) (at Technical College Blackburn) —J Ranson The Structure of the Alps (Lecture).

SATURDAY, MARCH 21

BRITISH MYCOLOGICAL SOCIETY (in Botanical Department University College), at 11 A M —Miss D Ashworth Development of Spores in Choanophoraceae —Miss M Brett Reversible Saltation in *Stemphylium* —P H Gregory The *Fusarium* Bulb rot of *Narcissus* —W M Ware Mushroom Growing Its Scientific and Practical Aspects

INSTITUTION OF MUNICIPAL AND COUNTY ENGINEERS (Yorkshire and North Western Districts) (at College of Technology, Manchester) at 2 30 —Dorman Long and Co Ltd The Building of the New Tyne Bridge, The Building of Imperial Chemical House and The Sydney Harbour Bridge

MATHEMATICAL ASSOCIATION (at Bedford College) at 3 —S Inman Contracted Methods in Arithmetic

ROYAL INSTITUTION OF GREAT BRITAIN at 3 —Lord Rutherford Recent Researches on the Alpha Rays (3).

RURAL RECONSTRUCTION ASSOCIATION (at 26 Bedford Square) at 3 —R. Borlase Matthews The Importance of Electrical Development to the Countryside —M Fordham Marketing and Employment

MONDAY, MARCH 23

ROYAL COLLEGE OF SURGEONS OF ENGLAND at 5 —R T Payne Demonstration on Pathological Specimens Relating to Diseases of the Gall Bladder and Extra hepatic Biliary Passages

INSTITUTION OF MECHANICAL ENGINEERS (Annual Meeting) at 6 45 Short Papers

INSTITUTION OF ELECTRICAL ENGINEERS (North Eastern Centre) (at Armstrong College, Newcastle upon Tyne), at 7

INSTITUTION OF ELECTRICAL ENGINEERS (South Midland Centre) (at Birmingham University), at 7 —J W Rissik and H Rissik Heavy Duty Rectifiers and their Application to Traction Substations

INSTITUTE OF FUEL (at Institution of Civil Engineers), at 7 30 —R A Burrows Self help in the Coal Industry

BRITISH KINEMATOGRAPH SOCIETY (at Film House Wardour Street), at 7 45 I Rowson Some Aspects of Camera Work in Hollywood

ROYAL SOCIETY OF ARTS, at 8.—Capt. A G D West The Recording and Reproducing of Sound (Cantor Lectures) (3)

ROYAL SOCIETY OF MEDICINE (Odontology Section) at 8 —Clinical Meeting

ROYAL GEOGRAPHICAL SOCIETY, at 8 30 —Dr C Christy Liberia in 1930

SOCIETY OF CHEMICAL INDUSTRY (Yorkshire Section) (Annual General Meeting) (at Leeds) —H J Pooley and others Discussion on the Activities of the Society

TUESDAY, MARCH 24

ROYAL SOCIETY OF ARTS, at 4 30 —Dominions and Colonies Meeting

ROYAL SOCIETY OF MEDICINE (Medicine Section), at 5 —Dr Janet Vaughan Dr S C Dyke Dr J F Wilkinson and others Discussion on The Value of Liver in Treatment

ROYAL COLLEGE OF PHYSICIANS OF LONDON at 5 —Sir William Willcox Toxic Jaundice (Lumleian Lectures) (2)

ROYAL INSTITUTION OF GREAT BRITAIN, at 5 15 —Dr C D Darlington The Cytological Theory of Heredity and Variation (3)

EUGENICS SOCIETY (at Linnean Society), at 5 30 —W Palin Elderton Heredity and Insurance.

INSTITUTION OF CIVIL ENGINEERS, at 6 —G C Minnitt The Washaway and Reconstruction of the Nerbudda Bridge on the Great Indian Peninsula Railway —The late P Allan The Georges River Bridge, New South Wales

INSTITUTION OF ELECTRICAL ENGINEERS (London Students Section), at 6 15 — R Appleyard Michael Faraday

INSTITUTION OF ELECTRICAL ENGINEERS (North Midland Centre) (at Hotel Metropole Leeds) at 7 —E S Ritter Picture Telegraphy

INSTITUTION OF ELECTRICAL ENGINEERING (North Western Centre) (at Engineers Club, Manchester) at 7 — C E R Bruce The Distribution of Energy liberated in an Oil Circuit Breaker, with a Contribution to the Study of the Arc Temperature

INSTITUTION OF ELECTRICAL ENGINEERS (Scottish Centre) (at North British Station Hotel Edinburgh), at 7

INSTITUTION OF ENGINEERS AND SHIPBUILDERS IN SCOTLAND (at 39 Elmbank Crescent Glasgow) at 7 30 — O Short Design and Construction of Marine Aircraft

QUEKETT MICROSCOPICAL CLUB (at 11 Chandos Street W 1) at 7 30 — Gossip Meeting

SHEFFIELD METALLURGICAL ASSOCIATION (at 198 West Street Sheffield), at 7 30 —J D Hannah Some Notes on the Selection and Examination of Materials for Driving Chain Manufacture

INSTITUTION OF CHEMICAL ENGINEERS (at Chemical Society) at 8 —C F Hammond The Concentration of Phosphoric Acid Solutions by Means of the Submerged Flame

ROYAL ANTHROPOLOGICAL SOCIETY at 8 30 —G D Hornblower Temples and Kings of Ancient Egypt

INSTITUTION OF ELECTRICAL ENGINEERS (East Midland Sub Section) (at University College, Nottingham) —W J Webb The Architectural Requirements of a Modern Electric Home

INSTITUTE OF BREWING (Scottish Section) (at Caledonian Hotel, Edinburgh) —Dr R H Hopkins Physical Chemistry of the Proteins and some Applications to Brewing Problems

INSTITUTION OF ELECTRICAL ENGINEERS (Irish Centre—Dublin) — Prof W Cramp The Birth of Electrical Engineering (Faraday Lecture)

WEDNESDAY, MARCH 25

BRITISH ASTRONOMICAL ASSOCIATION (at Sion College), at 5

INSTITUTION OF CIVIL ENGINEERS (Students Meeting) at 6 30 — J M Liddell Recent River wall Construction on the Thames

INSTITUTION OF AUTOMOBILE ENGINEERS (Manchester Centre) (at Engineers Club Manchester) at 7 — J E Arrowsmith Pressings for Automobiles

NORTH EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (Tees Side Branch) (Graduate Section) (at Cleveland Scientific and Technical Institution Middlesbrough) at 7 — A Brown The Construction of the Airship Base in Ismalia

NORTH EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (Graduate Section) (at Bolbec Hall Newcastle on Tyne), at 7 15 — *Debate That the Present Depression in the Engineering Industry is Largely Due to Inefficient Sales Organisation*

INSTITUTE OF CHEMISTRY (Belfast and District Section) (at Royal Belfast Academical Institution) at 7 30 —R T Shepherd Absorption of Gases in Electrical Discharge Tubes

ROYAL SOCIETY OF ARTS at 8 —Prof P Abercrombie The Kent Coalfields

BRITISH PSYCHOLOGICAL SOCIETY (Medical Section) (at Medical Society of London), at 8 30 —Dr M F J Lowenfeld A New Approach to the Problem of Psychoneurosis in Childhood

THURSDAY, MARCH 26

ROYAL COLLEGE OF PHYSICIANS OF LONDON at 5 — Sir William Willcox Toxic Jaundice (Lumleian Lectures) (3)

ROYAL INSTITUTION OF GREAT BRITAIN at 5 15 Prof J B S Haldane Respiration (6)

ROYAL SOCIETY OF MEDICINE (Urology Section) at 5 30 —Prof A von Lichtenberg The Principles and New Advances in Excretion Urography

OPTICAL SOCIETY (at Imperial College of Science and Technology) at 5 30 —T Smith (*a*) Secondary Conjugate Surfaces (*b*) Graphical Constructions for a Refracted Ray —A Whitwell Fused Bifocal Spectacle Lenses

INSTITUTE OF FUEL (South Wales Branch) (at South Wales Institute of Engineers Cardiff) at 6 — Major E Ivor David Local Generation of Electrical Power plus the Grid

INSTITUTION OF ELECTRICAL ENGINEERS at 6 — R Grierson The Electrical Heating of Buildings

BRITISH PSYCHOLOGICAL SOCIETY (Industrial Section) (at National Institute of Industrial Psychology) at 8 —Dr M Drury Smith The Idea of the thing as a whole in Certain Forms of Learning

FRIDAY, MARCH 27

ROYAL SOCIETY FOR THE PROTECTION OF BIRDS (at Middlesex Guildhall, Westminster) at 3 —Annual Meeting

INSTITUTION OF ELECTRICAL ENGINEERS (West Wales (Swansea) Sub Centre) (at Electricity Offices, Swansea), at 6

INSTITUTE OF FUEL (East Midlands Section) (at Technical College Derby) at 7 P H N Ulander The Power Consumption of Boiler house Auxiliaries

INSTITUTION OF MECHANICAL ENGINEERS (Informal Meeting) at 7 — Exhibition of Industrial Kinematograph Films

JUNIOR INSTITUTION OF ENGINEERS, at 7 30 —C E Prince Light Sensitive Work in Modern Industry

GEOLOGISTS ASSOCIATION (in Architectural Theatre, University College) at 7 30 — Prof L S. Palmer On the Pleistocene Succession of the Bristol District E M Venables Notes on the Geology of Felpham, near Bognor Regis

ROYAL SOCIETY OF MEDICINE (Epidemiology and State Medicine Section), at 8 —Dr A F MacCallan Trachoma its Importance as a World wide Disease

ROYAL INSTITUTION OF GREAT BRITAIN, at 9 —Lord Rutherford Helium and its Properties

SATURDAY, MARCH 28

ROYAL INSTITUTION OF GREAT BRITAIN at 3 —Lord Rutherford Recent Researches on the Alpha Rays (4).

PUBLIC LECTURES.

SATURDAY, MARCH 21

HORNIMAN MUSEUM (Forest Hill), at 3 30 — J E S Dallas Peasant Life in Alpine Districts

TUESDAY, MARCH 24

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL, at 5 15 —Dr C H Andrewes Immunity in Virus Diseases (2).

THURSDAY, MARCH 26.

BRITISH MEDICAL ASSOCIATION (Tavistock Square), at 5 15 —Prof Major Greenwood Nerves and the Public Health (Chadwick Lecture)

SATURDAY, MARCH 28

HORNIMAN MUSEUM (Forest Hill), at 3 30 —Prof J R Ainsworth Davies Fur bearing Animals in Canada

CONFERENCES

TUESDAY, MARCH 24

CONFERENCE ON THE PLACE OF SHEEP IN MODERN FARMING (at Rothamsted Experimental Station, Harpenden) at 11 30 A M —Chairman J Egerton Quested Speakers F A Thomson, J R Wood, A Lewis J Joyce Major V S Bland, H Edgar H W Drewitt, A C Hill, H G Miller

SATURDAY AND MONDAY MARCH 28 AND 30

SOCIETY FOR EXPERIMENTAL BIOLOGY (at Edinburgh)

Saturday March 28 (In Department of Zoology)

10 A M to 1 P M —J Hammond The Life of the Unfertilised Ovum

A J M Smith The Problem of the Vitelline Membrane (*a*) Gas Exchange and Osmotic Equilibria of the Infertile Hen s Egg

J Needham M Stephenson and D M Needham The Problem of the Vitelline Membrane (*b*) Lactic Acid Production in the Infertile Hen s Egg

J Needham The Problem of the Vitelline Membrane (*c*) The Osmotic Properties of the Isolated Membrane

H O Bull Conditioned Responses and Salmon Smolts

W H Pearsall and M Pilling The Physiology of Storage in the Apple

E C Barton Wright The First Sugar of Photosynthesis

(In Department of Animal Genetics)

2 15 to 3 45 —*F A. E Crew and L Mirskaia* (*a*) Genetic and Physiological Studies on the Hairless Mouse (*b*) Observations on the Aged Male and Female Mouse

B P Wiesner P G Marshall J M Robson H Taylor and R E Illingworth Recent Experiments on the Dynamics of the Sex Cycle

3 45 to 5 30 —Demonstrations

5 30 to 6 30 —E Boyd Experiments on Skin Transplantation in the Mouse

E M Gilroy The Effect of Arginine and Thyroxine on the Growth Rate of a Transplantable Tumour of the Mouse

Monday March 30 (In Department of Bacteriology)

10 A M to 12 15 P M — I J Blake Experimental Infection of *Salmo fario* by *Bacillus salmonicida*

A Cunningham and T Gibson Recent Work on the Filterable Gonidial Stages of Bacteria.

J J Mackie M H Finkelstein and H J Gibson The Natural Antibodies of Various Animal Species

J M Alston Analysis of Antigens on the Basis of Chemistry and Function

M H Christison Microbic Dissociation with Special Reference to the Tubercle Bacillus

12 15 to 1 —Demonstrations

(In Department of Zoology)

2 15 to 3 45 — A Walton Gas Storage of Mammalian Spermatozoa

A L Craig Bennett Observations on the Influence of Temperature on the Breeding of Animals

A Graham Temperature and *p*H Optima of Invertebrate Enzymes

3 45 to 4 30.—Demonstrations

4 30 to 6 —J W Gregor Experimental Methods in Taxonomy

V E McM Davey Inheritance of Colour in Certain Species of *Brassica*.

W Black Inheritance of Colour in the Potato Tuber

ANNUAL MEETING

MARCH 25, 26, AND 27

INSTITUTION OF NAVAL ARCHITECTS (at Royal Society of Arts).

Wednesday, March 25 at 10 30 A M —Lord Wester Wemyss Presidential Address

Sir Archibald Hurd British Sea Power, 1900 1930

M F Hay The Maierform of Hull Construction

Thursday March 26 at 10 30 A M —Sir Charles J O Sanders The Establishment of an International Load Line

J Foster King International Load Lines

L C Burrill Seaworthiness of Collier Types

At 2 30 —Prof W Hovgaard A New Theory of the Distribution of Shearing Stresses in Riveted and Welded Connexions and its *Application to Discontinuities in the Structure of a Ship*

F H Todd Further Model Experiments on the Resistance of Mercantile Ship Forms - Coaster Vessels.

Friday, March 27, at 10 30 A M —Dr H H Blache The Present Position of the Diesel Engine for Marine Purposes

H E Yarrow Water Tube Boilers in Some Recent Merchant Ships with Service Results.

W H Howden Some Modern Examples of Air Heaters

At 2 30 —E F Spanner Beam Frame Connexions.

SATURDAY, MARCH 28, 1931

University Entrance Scholarships for Science.

AT the Headmasters' Conference last December the following resolution was passed, with only four dissentients

"That this Conference regrets the degree of specialisation which the Science Scholarship Examination papers at Oxford and Cambridge demand from candidates, and wishes

(1) that in all Science Scholarship Examination papers the General Paper should be given a definite value, and

(2) that at least some Science Scholarships could be offered for which a less specialised course of Science would be required"

Recent correspondence on this subject in the *Times* points to the existence of an educational problem, but fails to produce any satisfactory solution Mr Fletcher, headmaster of Charterhouse and chairman of the Headmasters' Conference, deprecates the fact that boys who cannot afford to go to the university without a scholarship, often the best material at the start, are forced prematurely into an undesirably narrow groove, and implies that thus the probable future leaders of science are being brought up as "illiterate and premature specialists" He offers no constructive suggestion to remedy the evil, but hopes that university authorities may by his very importunity be urged to take action

In defence of Oxford, Mr C N Hinshelwood, of Trinity College, points out that in the examination held by a group of nine colleges, candidates must (1) offer at least three subjects selected from chemistry, physics, zoology, botany, mathematics, (2) take a paper in which are set passages for translation from four languages, (3) do a general paper, to which a very definite value is attached His account of the principles observed in making the awards renders it difficult to conceive how the examination could be improved

From Cambridge, Mr J T Saunders, of Christ's College, champions the educational value of science rightly taught, and directs attention to the importance of personal, as distinct from tutorial, influence in stimulating general culture

Among other correspondents, Dr F A Bather advocates that future endowers of scholarships should give the money to the schools and not to the colleges, Mr Knight, until recently headmaster of Sexey's School, Bruton, urges that the universities should reserve a fair proportion of available scholarships for candidates who have covered a wider curriculum, as indicated in paragraph (2) of the

Conference resolution, Prof A V Hill, admitting the disease and the difficulty of curing it, politely hints that the classical pot is every whit as black as the scientific kettle, and so on

It is generally admitted that, especially in chemistry and physics, the papers now set are of a more advanced character than was the case, say, twenty years ago But the improved equipment of school laboratories and the increase in the number of science masters per school render possible, nay, justify, the attainment of a higher standard of work at schools Moreover, natural science is essentially progressive The discoveries made during the present century have profoundly modified our ideas both in biology and in physical chemistry, and it is right that the rising generation be taught to view each subject in the light of the most recent knowledge Probably no school permits its pupils to specialise in any direction, scientific or other, until a school certificate examination has been taken This examination, though elementary, does at any rate ensure a certain minimum of general education, and by the time a pupil takes it his capacity for profiting intellectually by specialisation in a particular direction ought to be fairly evident

It must not be forgotten that all minds are not cast in the same mould, and that all do not mature at the same rate Some there are who, about sixteen years of age, show marked ability in classical and literary subjects and yet are complete failures in natural science Conversely, there are those who, by sheer perseverance in the uncongenial deserts of most of the compulsory subjects in the school certificate examination, at length reach the promised land and find their *métier* in one or more of the scientific subjects Similarly, those wide interests which constitute culture make no appeal to some, be they never so temptingly put before them—a silk purse was never yet made from a sow's ear, but why should the community be deprived of the good leather that it is capable of yielding? The boy who is, unfortunately, gifted in only one direction should surely be allowed to pursue it to the full

It is perhaps a counsel of perfection to urge that school curricula should be so wide as to afford to every pupil the opportunity of sampling many subjects, and thus of finding out where his true interests lie, though the personality of the teacher often goes far towards determining this Nevertheless, within the limits of the school certificate subjects, it should be possible to ensure logical thinking and ability to express thoughts and to describe facts in clear, concise, grammatical English, nor ought teachers in specialised, post-certificate subjects to permit written work to be presented in slipshod, illiterate form

There are several ways by which the cultural outlook of specialist pupils may be enlarged school societies debating, literary, musical, travel, and the like—all tend to prevent excessive narrowness, while short courses of lectures on, for example, great artists, musical composers, architecture, exploration, and so on, need make no violent inroads into the time-table, and yet serve to awaken interests the existence and quality of which can be tested in the general paper to which the Headmasters' Conference wishes a definite value assigned

What this value should be is not easy to decide Good essays in the general paper are known to have determined the award of science scholarships when there was little to choose between the scientific attainments of competing candidates But can it be maintained that a candidate who is *facile primus* in the science papers should be disqualified from election by a poor performance in the general paper?

Clause (2) of the resolution of the Headmasters' Conference presents practical difficulties "A less specialised course of Science" presumably connotes at least two subjects of the usual three, biology, chemistry, and physics, taught in schools Biologists are bound to have some preliminary teaching in both the other subjects, so it would not appear unreasonable to demand of them in scholarship examinations a knowledge of the elements of chemistry and physics It is, however, almost impossible for boys offering chemistry and physics to include biology in their *repertoire* Physics, other than elementary, demands considerable mathematical efficiency, hence the boy who selects physics as one of his subjects must make full use of the hours allotted to mathematics Biology is thus crowded out of his time-table

So long as competition exists, examiners will be prone to set questions on topics near the upper limit attainable by the candidates concerned, though it is sometimes possible to discriminate between candidates by means of relatively easy questions, allowing wide scope in the quality of the answers If representatives from the universities and from the Science Masters' Association could agree on reasonably high boundaries beyond which no question is to be set in scholarship examinations for, say, the next ten years, and if the universities would appoint moderators to supervise the papers proposed by college tutors for scholarship examinations in order to secure that the questions lie within the agreed limits, perhaps the Headmasters' Conference would find less to deplore

Chemistry in Three Dimensions

Stereochemie Von Georg Wittig Pp xi+388 (Leipzig Akademische Verlagsgesellschaft m b H, 1930.) 25 gold marks

THE centenary of Kekulé's birth was celebrated in September of 1929, and many chemists who were present on that interesting occasion welcomed the opportunity which Prof Pfeiffer gave them of inspecting those old models with the black ball attached to four metal rods directed towards the corners of a regular tetrahedron Those were, in fact, the identical models upon which the youthful van 't Hoff had gazed with wonder, and which doubtless contributed in no little measure to the inspiration which the old university town gave him, for van t Hoff cherished to the end a love for Bonn "In Leiden", he wrote, "war alles Prosa, die Umgebung, die Stadt, die Menschen In Bonn, alles Poesie!" During van 't Hoff's sojourn in Bonn in 1872–73, Kekulé had already gathered round him a band of enthusiastic workers, including men like Franchimont, Spring, Wallach, and Zincke, but the independent Dutchman did not display the slightest inclination to join this illustrious circle, and thus, naturally enough, Kekule lost interest in him So off to Wurtz and to Paris, but the seed for one of the greatest conceptions in chemistry had fallen on fertile soil

Since the formulation of the doctrine of the asymmetric carbon atom by van 't Hoff and Le Bel in 1874, the progress of stereochemistry with all its ramifications has been so rapid and so well sustained that it is an impossible task in the brief scope of some 400 pages to give any account of these advances which can be at once comprehensive and adequate Dr Wittig has frankly recognised this difficulty The literature published after 1904—the date of the appearance of Werner s "Lehrbuch der Stereochemie"—is dealt with in much greater detail than is the earlier work, and in order to effect further economy of space, many branches are perforce either omitted altogether or scarcely mentioned at all Fortunately, an account of the progress of the study of the Walden inversion is given by Walden himself in his "Optische Umkehrerscheinungen", and chemists who are interested in this problem should consult this résumé Thus, by dealing very briefly with certain fundamental problems, the author has allowed himself ample space for other sections, notably those concerned with co-ordination compounds and with crystal structure Indeed, the account of Werner's brilliant researches is altogether admirable, and it is written with remarkable clarity Incidentally, mention is made of that unique optically active compound containing no carbon and having $[M]_{5600}$-47,000°, a high value which should appeal to those chemists who quote molecular rotations

Dr Wittig shows too little discrimination in sifting those aspects which are really important from those which are merely trivial It would be easy to give many examples in support of this criticism, but one may suffice The introduction of the camphor sulphonic acids for resolving externally compensated bases proved in the hands of Pope to be an experimental contribution of outstanding service Not only did it enable him to break entirely new ground in the stereochemistry of nitrogen, sulphur, and other elements, but also Werner and many others who followed later would have been seriously incommoded if the application of those camphor acids on the part of the English investigator had not paved the way The references on pp 37 and 169 scarcely suggest that Pope s contribution had any value at all This is one reason why this book should not be placed in the hands of a beginner, who might also miss the romance engendered by a close survey of the earlier history Why, for example, should that dramatic episode of the conversion of the sceptical Biot by Pasteur be omitted? It is an old story which can be told again and again without losing its charm

I find throughout Dr Wittig s book a distinct lack of balance in the whole treatment, the picture is presented all too often out of its proper perspective For example, in no country more than in Great Britain has the study of optically active compounds been prosecuted with greater zeal, but we look in vain for an adequate recognition of the contributions of those pioneers, Purdie and P F Frankland Purdie's name is not even mentioned, although the resolution of lactic acid by the addition of a nucleus of *d*- or *l*-zinc ammonium lactate to a supersaturated solution of the inactive double salt is an unusual and an elegant method which still remains the most practical one for preparing the optically active lactic acids by the kilogram Purdie's methods of resolving lactic and alkyloxypropionic acids by alkaloids, as well as Frankland's resolutions of glyceric acid, are models of exact experimenting which, even in these days of hurried publication, could be read and imitated with very great advantage by those who wish to obtain their substances in a condition of optical purity Nor is there any reference to those experiments on optically active esters which led to the discovery of the silver oxide

method of methylation, which has proved its value (in the hands of Irvine and others) in the chemistry of carbohydrates Again, less than justice is done to Frankland's comprehensive work on the connexion between optical activity and chemical constitution, and to the work of his pupils, Patterson and Pickard, in the same field

It is a matter of some regret that Dr Wittig has, for lack of space, so little to tell us about the application of stereochemical ideas to enzymatic actions The reader will, therefore, have to go elsewhere if he wishes information on work such as that of Neuberg, for example We miss a reference to the ingenious experiments on asymmetric reduction and dismutation, and on the formation of phenylacetyl carbinol by the addition of benzaldehyde to a sugar in the process of undergoing fermentation Whether the equation

$$C_6H_5\ CHO + CH_3\ CHO = C_6H_5\ CH(OH)\ CO\ CH_3$$

can be accepted for the latter action is a matter for debate, but in any event the asymmetric formation of the lævorotatory ketol by the enzyme carboligase is an observation of striking originality, and one which emphatically should find a place in every modern text-book of stereochemistry

A few mistakes have been noticed , for example, on p 21 *Bacillus œthalticus* should be *Bacillus ethaceticus*, and on p 63 $C_{10}H_9$ should be $C_{10}H_{19}$ The scheme at the top of p 53 is incomplete, the conversion of the amino alcohol into the ketone not being indicated, whilst the real point of interest, namely, the retention of optical activity during the semipinacolinic changes from the amino alcohol and the glycol, is missed altogether The asymmetric synthesis of mandelic acid was never effected as described on p 40 The statement on p 169 that Le Bel obtained the optically active methyl-ethyl-propyl isobutyl ammonium chloride is incorrect , the first quaternary compound of this type was prepared by Pope in 1899

In the index and throughout the text the names of authors should be revised , designations such as B Cohen, O Forster, A Guye, F Landolt, H Perkin, S Patterson, F Frankland, etc , enable us to recognise the authors, but they have a strange ook !

In spite of some defects, this book can be commended most cordially to those who are not actually beginners in the study of stereochemistry Dr Wittig has given us by far the best account of this subject which has been published within the past twenty-five years, and we ought to be very grateful to him ALEX MCKENZIE

Star Clusters and the Galaxy

Star Clusters By Harlow Shapley (Harvard Observatory Monographs, No 2) Pp xi + 276 + 3 plates (New York McGraw-Hill Book Co , Inc , London McGraw-Hill Publishing Co , Ltd , 1930) 15*s*

IN 1915–18, Dr Shapley published a remarkable series of researches on globular clusters which brought these remote objects into the forefront of astronomical interest His results indicated an extension of the flattened system of the galaxy about ten times greater than had previously been adopted This was the beginning of a phase in astronomy which its critics might describe as megalomania The same method has since been applied to the still more distant spiral nebulæ, and these have tended to displace the globular clusters in their appeal to our imagination From the observational point of view, however, there is no comparison between the stage of advancement of the two subjects As regards the spirals, our systematic knowledge is summed up in a fairly trustworthy calculation of the size and distance of three or four of the nearest of them, a guess at the distances of the remainder, and the astonishing fact that almost without exception they are running away , as regards the star clusters, we have before us Shapley's monograph, closely packed with statistics and individual studies, with a wealth of problems and deductions which interact with and illuminate our knowledge of the stars in our immediate neighbourhood

In the bibliography at the end of the book, Shapley's share amounts to 150 papers It was time, therefore, that he should make this attempt to consolidate the gains to knowledge during fifteen years of assiduous research Primarily the book is a mine of information where we may find set forth the latest position with regard to the innumerable problems which the study of star clusters has provoked One of the most intriguing features of the work, recognised at the outset, has been that in some respects our knowledge of the distribution and statistics of stars in these systems 10,000-50,000 parsecs away may be much more advanced than our knowledge of the stars at less than 100 parsecs distance The reason is that the distances of the nearer stars are found individually with great labour and uncertainty, whereas in observing a globular cluster a single determination of distance applies to the whole system The principal method of finding the distance is by measuring the apparent magnitude of the Cepheid variables

contained in the cluster, comparing the apparent magnitude with the known absolute magnitude of a Cepheid of the same period, the distance is obtained immediately, provided that absorption of light in interstellar space in inappreciable The method was first used by Hertzsprung to find the distance of the lesser Magellanic Cloud Shapley has found the distances of twenty out of the ninety known globular clusters in this way Distances of the remainder are estimated by more doubtful procedure Shapley uses distances determined by either method promiscuously We think this is unfortunate, for even if the validity of the less direct methods is admitted, it is clear from his own diagrams that the distance obtained for an individual cluster is very rough, and its value is mainly statistical

The assumption that the light of the globular cluster suffers no important absorption in reaching us is probably legitimate, but the monograph may give an undue impression of the strength of the evidence Actually the main evidence for transparency (none too strong) is outside the scope of the monograph, being based on our general knowledge of the density and state of the interstellar cloud Shapley showed that the light coming from star clusters is not reddened by scattering, and thus settled a long outstanding question but with our present knowledge, both observational and theoretical, that interstellar matter is ionised, we cannot infer absence of absorption from absence of reddening In short, Shapley's observational fact (absence of reddening) is countered by another observational fact (existence of ionisation) and the problem reverts mainly to theoretical investigation Further, we know that about two per cent of the sky is covered with opaque matter, and although there appears to be in general a rather sharp transition from complete opacity to nearly perfect transparency, it will be fortunate if all the ninety clusters escape the transition zones

There is a startling heading to §51, "A Theoretical Period-Luminosity Relation for Galactic Cepheids" There is a theoretical period-density relation described elsewhere in the book, but hitherto theory has been baffled to find any explanation of the period-luminosity curve, which is a quite independent correlation On examination, we find that the heading has no real justification, and the section deals with the relation of the period-luminosity curve to another equally empirical curve, in fact, the argument has gone round the circle, since the data embodied in these two empirical curves were used to verify the original period-density relation The comparison of "observed and theoretical period luminosity relations" on p 148 is an alternative way of presenting the more usual comparison of the observed and theoretical period-density relations

Shapley concludes that the minimum diameter of the galactic system is 70 kiloparsecs, with a thickness about one-tenth as great Our distance from the centre is about 16 kiloparsecs, this is in satisfactory accordance with estimates ranging round about 10 kiloparsecs based on the phenomenon of galactic rotation I see no escape from dimensions of this order, yet it raises a difficult question when we come to compare the galactic system with the spiral nebulæ I think it was Shapley who remarked that if the spirals are 'island universes' our galaxy is a 'continent' The discrepancy in size between our galaxy and the external galaxies cannot be attributed to errors in the determination of the distances, for the same method is used for both and a systematic error would expand or contract them equally If absorption of light in space is appreciable, the discrepancy becomes still greater

Shapley now proposes the view that our system is not a single spiral but comparable with the clusters of spirals in Coma Virgo and in Ursa Major, this reverses the difficulty, for their dimensions appear to be much larger than those of the galaxy If we accept this view, we have to disregard the evidence of galactic rotation, the observed rotation is of differential type which would quickly shear any individual sub-system, and it cannot be interpreted as rotation of a number of separate star-clouds round a common centre We can only wait for further light on this perplexing problem

A S EDDINGTON

Biology and Human Life

The Science of Life By H G Wells, Julian Huxley and G P Wells Pp xvi + 896 (London, Toronto, Melbourne and Sydney Cassell and Co, Ltd, 1931) 21s net

THIS is in several ways a remarkable book, as its authorship would lead us to expect, for it gives us in one volume a competent comprehensive survey of the whole of biology—physiological, morphological, embryological, and evolutionary, it is written so that it can be 'understanded of the people' and with a sparkle that engages the attention, and it is one of the few books, heralded by Sir Richard Gregory's "Discovery", which make the reader feel that science is not only for illumination,

N 1

but also for "the relief of man's estate", as Bacon phrased it If, as we believe, mankind is at the dawn of a new era—the biological era, when an all round appeal will be made to the biological sciences, as already to the physical, for guidance in the control of human life—then the big book of Wells, Huxley, and Wells will come to be regarded as an instalment of the relevant 'Law and Prophets' Along with biology, we are, of course, including psychology, for these two sciences are becoming almost as inseparable as chemistry and physics No doubt the last scientific word will be with sociology, but that science, though born two millennia ago, has not yet come of age

It may be said that the appeal to biology began very long ago when the early patients sought the aid of the early physicians, but this was an appeal to an art rather than to a science For, while many of the physicians, from Hippocrates and Galen onwards, were biologically minded in a high degree, biology is a modern science and a widespread appeal to biology as a science is still incipient The recent establishment of a professorship of social biology in the University of London is a natural supplement to a eugenics laboratory, both expressing a movement of which Galton and Pasteur were pioneers Thus, while we appreciate "The Science of Life" for its wide reach, its educative lucidity, its fair mindedness, its freshness of presentation, its arresting figures, and so on, we appreciate it most because the authors have had the courage of their convictions and have not hesitated to proclaim, as their particular gospel, that the utilisation of biological knowledge can do much to save man amid his sea of troubles We do not mean that this book stands alone in this respect, but it is perhaps the largest comprehensive treatise in which 'biology for life' is a dominant note Cowdry's "Human Biology and Racial Welfare" (1930) is, to our thinking, a fine collection of specialised propagandist tracts, but the book before us is a treatise on biology, written primarily for the scientific instruction of the people, yet ever sounding the note of practical applicability It would have pleased T H Huxley, who was so clearly convinced of the indispensableness of applying science to life, declaring "that there is no alleviation for the sufferings of mankind except veracity of thought and of action, and the resolute facing of the world as it is" The same idea was finely expressed in a convincing address on Jan 23 last by Sir Walter Morley Fletcher, which ended with the prophetic sentence "that we can find safety and progress only in proportion as we bring into our methods of statecraft the guidance of biological truth"

It is time, however, to give some indication of the scope of this big book, and that is not difficult, for there is a progressive plan It begins, physiologically, with the living body, it surveys, morphologically, the forms or patterns of life, it insists that the key to intelligibility is the concept of evolution, it discusses the factors in individual development and in racial history (ontogeny and phylogeny), it sketches the ascent of life throughout the ages, the adventures and achievements of the ever-changing Proteus Then the book begins again, as it were, from the vantage ground it has gained, and envisages the pageant and drama of life—a fine introduction to ecology But the drama has its tragic side and this leads to a consideration of disease and the present very chequered health of *Homo sapiens*, who so often belies his specific name But the activities, the ascent, the adventure, and the drama of life have all their subjective aspect, as real as the objective, though more elusive, and the eighth book of the treatise deals with behaviour, feeling, and thought, leading on to a tentative monistic theory (not so far from the ancient hylozoism !)—the conception of "a single universal world stuff with both material and mental aspects, of which, so far as we know, life is the crowning elaboration, and human thought, feeling, and willing the highest expression yet attained" The concluding 'Book' deals with the biology of man, and, with a bow to sociology, ends on a melioristic note—"Life under Control"

"The Science of Life" rather disarms criticism by its frankness and sincerity and by its freedom from dogma Thus, in discussing the trans scientific question of purpose in or behind evolution, the authors state (1) the view "of Bergson and Shaw" that organisms work out their own evolution purposively, if not even purposefully, and (2) "the Creationism-up to date" of some modernist theologians, that the world of life is the realisation of a divine purpose, which was dynamically embodied in the original institution of the order of Nature When the reader has got these post Paleyian views before him as clearly as may be, he is told that "The Science of Life" must say "No" to the first theory, and cannot say "Yes" or 'No" to the second Personally, we are not inclined to be bluffed by a too abstract science, as if it were the only pathway towards truth, but we must admit that the authors occupy a clear headed and reasonable position—that biology, as biology, has no pronouncement to make on the

validity of the philosophical or religious concept of a purpose behind evolution

Though the book runs to nearly 900 pages, that is not much for an appreciation of the whole gamut of life So we are not inclined to say that there should have been more about enzymes and less about the humorous "Margery" and the teleplasm she produces from her mouth We are sure that the authors must have thought out very carefully what seemed to them the best utilisation of the available space, and their restraint, relaxed just a little perhaps for "Margery", is admirable

In reading this remarkably successful presentation of the essentials of biology, our pleasure has been occasionally interrupted by finding a crumpled roseleaf, but it is in no carping mood that we give just a few illustrations "The Science of Life" is certainly not an apsychic biology, yet why does it insist that the body is a machine, and elaborate a comparison which has eventually to be withdrawn as inadequate? Similarly with the use of the word 'mechanism' for the nervous system and the like The authors are all right, but will their readers be? If biologists say 'machine' often enough, people will begin to believe that they mean what they say In this particular case, we think that would be a pity, for we agree with the authors that an organism is more than mechanism

A larger crumpled roseleaf is the picture of random variations and blind selection No doubt there are saving clauses and corrective illustrations, but some readers will be apt to relapse to the old nightmare view of evolution as a chapter of accidents, which it certainly is not For many variations are orthogenic, and many are obviously congruent with the already established organic architecture and metabolic routine Many express themselves in accordance with laws of growth and conditions of organic stability How many plant variations in the present (and presumably in the irrecoverable past) are shortenings or elongations of the vegetative or floral axis! Similarly, many animal variations are shortenings-down or lengthenings-out of particular arcs on the general life-curve or trajectory And so on at great length, for the authors know well that a very strong case can be made out for the frequency of definiteness in variation

Then as to natural selection, it is inadequately summed up in such words as "automatic" and "blind" How often the organism tries to play its hand of hereditary cards, endeavouring after well-being It is often automatically selected, but it often deliberately selects Many an able-minded bird or mammal is a factor in its own evolution, though it has no prevision of more than an immediate goal Again, the general reader requires to be told that the everyday natural selection of nuance variations, though in a sense "blind", is a sifting in relation to an already established *systema Naturæ* of intricate and stabilised inter relations

Then again, while we agree with a useful passage on the seamy side of evolution, which certainly includes, as Ray Lankester so well insisted, its degenerations and retrogressions as well as its advances and achievements, we cannot agree with the statement that "we find throughout the rest of life parallels to the diseases that haunt our own" On the contrary, we are prepared to defend the thesis that wild Nature (that is, apart from man's interference) is characteristically marked by exuberant positive health, while in civilised society diseases are rife and sub health is becoming almost normal!

But enough of these minor criticisms, for we welcome the book with heartiness It is an achievement of popular exposition in the best sense (and many professional biologists would do well to read it), it is written with learning and lucidity, and permeated with the idea of evolution, including a human evolution which will continue the more rapidly the more it is inspired by the science of life

Our Bookshelf

Reports of the Progress of Chemistry Issued by the Society of Chemical Industry Vol 15, 1930 Pp 758 (London Society of Chemical Industry, 1931) 7s 6d to members, 12s 6d to others

COMMONPLACE as the phrase has become, of this series of reports it may, and indeed should, be said that no chemical library ought to be without it The flood of literature which descends upon students and practitioners of chemistry grows ever greater, and a correspondingly warmer welcome is given to authoritative surveys The annual report on the progress of applied chemistry during 1930 is invested with added value in respect of its early publication, for it has been made available six weeks earlier than the corresponding date of publication last year

Applied chemistry is surveyed in twenty-five chapters The following are by the same contributors as for 1929 General, plant, and machinery (R Edgeworth Johnstone), mineral oils (A E Dunstan), fibres, textiles, cellulose, and paper (J C Withers), iron and steel (C O Bannister), non ferrous metals (A R Powell), electro chemical and electro-metallurgical industries (H T S. Britton and [1930] R A Robinson), soils and fertilisers (E M Crowther), sugars, starches, and gums (L Eynon and J H Lane), fermentation

industries (H L Hind and F E Day), foods (L H Lampitt), fine chemicals and medicinal substances (E Stedman) Other sections are fuel (H J Hodsman and A Kay), gas, carbonisation, tar, and tar products (J Macleod and T A Wilson), colouring matters and dyes (L J Hooley), bleaching, dyeing printing, and finishing (A J Hall), acids, alkalis, and salts (P Parrish and F C Snelling), glass (M Parkin), refractories, ceramics, and cements (J H Chesters and W J Rees), oils, fats, and waxes (H M Langton), paints, pigments, varnishes, and resins (G C Attfield, J O Cutter, L R Hickson, and H Causer), rubber (T L Garner), leather and glue (R H Marriott and H Phillips), sanitation and water purification (A Parker), photographic materials and processes (A Batley and E E Jelley), explosives (J Weir) Consideration of essential oils is deferred until next year

There is much information of interest to the general scientific reader, for example, it is recorded that the price of platinum is now below that ruling in 1914, that the extraction of rhenium, rarest of metals, is being operated commercially in Germany, and that the 'talkies' have stimulated research on photographic emulsions The chapter on sanitation and water purification deserves special commendation, for although the general standard of the reports is high, some tend more than others to become an expanded list of references It could be wished, too, that every reporter would survey work which, although of obvious industrial importance, has been classified for purposes of abstract publication as 'pure' chemistry A A E

Von Zahlen und Figuren Proben mathematischen Denkens für Liebhaber der Mathematik Von Prof Hans Rademacher und Prof Otto Toeplitz Pp vi + 164 (Berlin Julius Springer, 1930) 9 60 gold marks

It has been rightly said that the high walls built up round mathematics by the signs of integration and summation, cause mathematics to be a permanent mystery for the average thinking person It is true that a thorough insight into higher mathematics requires special training, yet within these abstruse theories, there must be some parts and some examples, at least, which, properly explained, could enable non experts to peep through the complex texture of mathematics, and derive thereby some measure of enjoyment This is the spirit which underlies the little work under notice Although this book will teach nothing new to mathematicians, it will be found most interesting and helpful by those who are interested in mathematics Without using anything but logic and the most elementary notations, the authors are able to guide one through the mysteries of the prime numbers, of incommensurable lines and irrational numbers, the theory of aggregates and the paradoxes of transfinite numbers, the doctrines of the polyhedra and the measurement of the circle Although their exposition is based on mathematical facts, the authors lay more stress on the general form and method of the questions treated, while occasional historical remarks add to their interest Thus, instead of showing the pragmatical aspects of mathematics, or their philosophical importance, the book emphasises the internal and structural characteristics of pure mathematics The student of logic, in particular, will find in this very able book an ample field for his speculations T G

Synthèses et catalyses industrielles fabrications minérales Par Prof Paul Pascal Deuxième édition Pp vi + 456 (Paris Hermann et Cie, 1930) 70 francs

Prof Pascal's book is divided approximately into two parts, the first dealing with nitrogen compounds and the utilisation of atmospheric nitrogen and the second with sulphuric acid The treatment is detailed and the theory of the processes receives special attention, so that the book is particularly useful in supplementing the more technical treatises. A very brief treatment of hydrochloric acid is given, in which the modern synthetic process receives most attention The references to the literature are very incomplete, and many important special treatises which could be consulted, in amplification of the various sections, are not mentioned

Although the author begins with an account of the "Nitrogen Problem", this is somewhat out-of-date, since it does not make clear that the real nitrogen problem at the present day is an economic one There is now no possibility of a shortage of fixed nitrogen, the problem is how to sell it Every country is, or shortly will be, self-supporting, and, as the newer processes are installed, the competition with the older will become more and more acute The trouble will increase as time goes on and the economic difficulties of over-production, which were considered visionary during the War, will become more and more menacing

Some Dogmas of Religion By Dr John McTaggart Ellis McTaggart Pp lii + 299 (London Edward Arnold and Co, 1930) 6s net

Messrs Edward Arnold and Co have done a valuable service in issuing a new and cheaper edition of the late Dr Ellis McTaggart's famous book, with a delightful introduction by Dr C D Broad "Some Dogmas of Religion" has been long out of print (it was first published in 1906) and second-hand copies have been difficult to find and expensive to buy Of this work Dr Broad says "In many respects it is a model of popular philosophical writing It presupposes no knowledge of philosophy, it is written with admirable clarity, and abounds with apt and amusing illustrations, and it deals with problems which have interested almost all intelligent men in all ages" It was McTaggart who said that the man who has no religion cannot have a bad one, and it was he who expressed the hope that "a time may come when metaphysics may attain the same certainty in a higher sphere which is now often reached by science in a lower sphere" It is well known that McTaggart managed to combine atheism with a belief in immortality and the Church of England. But he was what has become more rare nowadays; he was a serious thinker

Letters to the Editor.

[The Editor does not hold himself responsible for opinions expressed by his correspondents Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE *No notice is taken of anonymous communications*]

Formation of Methyl Alcohol by the Direct Oxidation of Methane

THE isolation and identification of the primary oxidation product of a hydrocarbon is so crucially important from the point of view of the theory of hydrocarbon combustion that no effort has been spared to overcome the experimental difficulties involved For, although there is considerable agreement that the main course of the oxidation proceeds in accordance with the hydroxylation theory, during recent years there has been some controversy as to whether the *initial* product is an hydroxylated molecule or a peroxide

Hitherto the cumulative weight of evidence, both direct and indirect, has been much more in favour of the initial formation of an hydroxylated molecule rather than that of a peroxide Thus the initial formation of ethyl alcohol by the interaction of ethane and ozonised oxygen at 100° C, the results of recent studies of the slow oxidation of ethane, the formation of acetaldehyde (by intramolecular change from vinyl alcohol) during the initial stages of the slow combustion of ethylene, and what is known concerning the explosive combustion of methane at high initial pressures, have all pointed unmistakably in that direction Nevertheless, until recently, all efforts to isolate the corresponding alcohol from the initial products of the slow interaction of one of the simpler paraffins with oxygen have been frustrated, apparently because under ordinary conditions the further oxidation of such an alcohol to the di-hydroxy stage occurs so rapidly Hence upholders of the hydroxylation theory have always postulated an initial 'non stop run' through the mono hydroxy to the di-hydroxy stage

Since the publication, in November last, of the results of a reinvestigation by Mr S G Hill and myself of the slow combustion of ethane (*Proc Roy Soc*, A, **129**, p 434), which showed that the initial product was not a peroxide but either ethyl alcohol or some less oxygenated body, Dr D M Newitt and Mr A E Haffner have succeeded in obtaining substantial quantities of methyl alcohol by the direct interaction of oxygen and methane at temperatures of 360° and pressures of about 100 atmospheres Under such conditions, and using a mixture initially containing methane and oxygen in the ratio 9 1, interaction was complete in a few minutes, about 17 per cent of the methane burnt was recovered from the products as methyl alcohol, another 0 6 per cent as formaldehyde, and the remainder as oxides of carbon and steam No hydrogen was liberated, and not even a trace of peroxide formed The methyl alcohol formed was isolated and identified by converting it into both methyl salicylate ('oil of wintergreen') and methyl *p* nitro benzoate (m p 95°), and it was estimated as methyl nitrite A full account of these very important experiments will be published in due course by Dr Newitt and Mr Haffner, who are to be congratulated on having thus shown conclusively that the slow oxidation of methane proceeds throughout in accordance with the hydroxylation theory

Fine Structure in the Hydrogen Band Lines

WE have recently had an opportunity of examining the spectrum of H_2 in a large Hilger quartz spectrograph crossed by a reflection echelon The method, of which an account by one of us (W E W) is being prepared for publication elsewhere, gives a record of the structure of all the lines of fair intensity So far we have only had time to examine a small number of typical lines, but the results are very interesting The alternate strong lines of two typical bands which end on the $2p\,{}^3\Pi_{ab}$ levels are all found to be double with the weaker component on the long wave length side (No description of the bands ending on the $2p\,{}^3\Pi$ levels has yet been published, but an account of these band systems by Richardson and Davidson has been communicated to the Royal Society) For example, in the $0 \rightarrow 0$ band of $3d\,{}^3\Sigma \rightarrow 2p\,{}^3\Pi$ we find that the $Q1$ line 5931 368 is definitely double, the components having an intensity ratio of about 3 to 1 and a separation $\Delta\nu$ about 0 21 wave number $Q3 = 6002\ 816$ is an incompletely resolved doublet with $\Delta\nu$ about 0 17 $R2 = 5938\ 620$ is an unresolved doublet with $\Delta\nu$ about 0 11 $R4 = 5982\ 561$ is not a simple line, but it is too weak and hazy to estimate the separation In the $1 \rightarrow 1$ band of the same system $Q1 = 6021\ 273$ is a very clear doublet with intensity ratio about 5 to 3 and $\Delta\nu$ about 0 21 $R2 = 6027\ 977$ is an unresolved doublet with $\Delta\nu$ about 0 08

We can compare the foregoing with typical lines of the $0 \rightarrow 0$ band of the a system $3p\,{}^3\Pi_{ab} \rightarrow 2s\,{}^3\Sigma$ [1] $Q1$ and $R0$ appear to have a very close satellite on the *short* wave length side of the main line $Q2$, $Q3$, $R2$, $R3$ are fairly sharp lines, but not so sharp as some lines in the spectrum $R1$ is a doublet with the weaker component on the *short* wave length side, intensity ratio about 3 to 10, and $\Delta\nu$ about 0 22 Unless this $R1$ is a blend with an unclassified line, these results mean that $3p\,{}^3\Pi_b$ is complex with the stronger level lower (as in $2p\,{}^3\Pi_{ab}$) and so is $2s\,{}^3\Sigma$ but with the weaker level lower The comparative magnitudes of the triplets (which we have only resolved into doublets run $2p\,{}^3\Pi_{ab} > 3p\,{}^3\Pi_b \approx 2s\,{}^3\Sigma > 3p\,{}^3\Pi_a$ If $R1$ is a blend the width of $2p\,{}^3\Pi$ is much greater than that of the other levels, but the remaining conclusions would require reconsideration

On the other hand, typical lines of the singlet systems such as 4856 553 ($= 0 \rightarrow 1\ P5$ of $3d\,{}^1\Pi_a \rightarrow 2p\,{}^1\Sigma$) 4873 010 ($= 0 \rightarrow 1\ Q3$ of $3d\,{}^1\Pi_b \rightarrow 2p\,{}^1\Sigma$), and 4822 94 ($= 2 \rightarrow 4\ R3$ of $3d\,{}^1\Sigma \rightarrow 2p\,{}^1\Sigma$) are sharp lines with no evidence of structure beyond temperature breadth and are definitely sharper than any of the lines so far considered This is not due to some accidental circumstance connected with the different region of the spectrum in which they lie For example, 4849 303, which is $0 \rightarrow 0\ R1$ of 4 (or 3)$p\,{}^3\Sigma \rightarrow 2s\,{}^3\Sigma$, and lies near these lines, is complex and asymmetric with the bulk of the energy not in the centre 4838 242, which is $R3$ of the same band, is similar to the $R1$ line except that it is weaker

The measurements given above are of a preliminary character We have a plate which looks better than the one on which they were made and we hope to improve on them The limit of our resolution is set by the natural temperature width of the lines, it is nowhere near the limit of the instruments employed We cooled our discharge tube in liquid air No doubt better results could be got with liquid hydrogen, but this is not available

These observations firmly establish the correlation between the spectrum of molecular hydrogen and that of atomic helium

The Meaning of Existence

WHAT Sir James Jeans says (NATURE, Feb 28, p 304) is, of course, quite true, but it scarcely answers Prof Muirhead's question May I try to explain what existence means in physics?

Primarily, it means the truth of some law having the form which defines a substance or object To say that silver exists is simply to declare that it is possible to demonstrate experimentally the association of the 'properties of silver' a certain density, melting point, and so on No serious person during the last fifty years has believed that the ether exists in this sense

Secondarily it means the truth of some theory A theory is not true unless (*a*) true laws can be deduced from it and (*b*) its hypothesis is intrinsically plausible This intrinsic plausibility is often derived from analogy with laws, if the laws from which it is derived are of the aforesaid form, the theory implies the existence of something Kelvin held that the ether exists because he believed in a theory the hypothesis of which had an intrinsic plausibility arising from an analogy with the laws describing the oscillations of a continuous medium That theory is now known to be false on ground (*a*), Kelvin's ether, therefore, does not exist But another theory has been put forward the hypothesis of which is a set of equations having an imperfect analogy with those describing the geometrical laws of space—which might be occupied by a continuous medium This theory is certainly true on ground (*a*) Some of us (including Sir James Jeans, I think) do not feel that the theory derives any intrinsic plausibility from this loose and indirect connexion with a continuous medium, we therefore reject the existence of the ether on ground (*b*) Others feel that it does, the idea of a continuous medium filling all space helps them to understand and believe relativity, for them both (*a*) and (*b*) are satisfied, and they hold that the ether exists Since the difference is one of personal taste (not as Eddington suggests, of words), there is no way of deciding between us

Two comments may be added (1) Physicists do not apply these criteria of existence consciously, they can be brought to light only by examining what physicists do believe to exist That is inevitable, for physics does not arrive at truth by formal reasoning based on fixed principles, it employs reasoning only to expound and to co ordinate conclusions reached by some more instinctive process (2) Existence in the physical sense has, of course, no meaning outside the region of experience that can be analysed into laws, and it is hopeless to explain what physical existence means to anyone to whom a law is not a primary and unanalysable conception NORMAN R CAMPBELL

155 Hagden Lane,
Watford Herts, Mar 1

I HAVE to thank Sir James Jeans for his courteous reception (NATURE, Feb 28, p 304) of my recent communication in these columns I had no intention of starting metaphysical hares in this field, but merely to express my agreement with him in holding that physical discussions are also apt to have their hares unless we begin with definitions of our terms His very interesting letter brings this home from the side of the contrast between the physicist of forty years ago with his assumption of "a vast independent universe of concrete machinery, unthinkingly and unconsciously accepted as his universe of discourse", and the scientific worker of to day, who finds his universe of discourse in "a phenomenal universe as apprehended by his brain" Though I should perhaps use other terms for the latter, I think that this well describes the change in the intellectual atmosphere brought about by recent developments in physics, to which I began by alluding in my former letter The "vast independent universe of concrete machinery" had not only established itself in the mind of the physicist of those days as independent, but also it was endangering the independence of all other universes by reducing them to appanages of itself, as the only reality, containing the "promise and potency" of all other forms of existence

Since then, not only have other universes (for example, those of mind and its creations in art, law and morality, science itself, to mention no others) staked out claims of their own in a lateral direction, but also physics itself, in extending its work vertically, has struck on a world to which the old conception of "concrete machinery" seems to be no longer applicable and the method of behaviour of which has to be expressed in quite other terms How this world is to be co ordinated with that of concrete machinery is, I suppose, one of the questions that at present occupy and are likely long to occupy the foremost scientific workers

What Sir James Jeans, among others, as I understand him, has suggested, is the paradoxical conclusion that, in thus deepening the view of its own universe, physics has revealed analogies between it and other universes that *prima facie* belong to an altogether different order, and has thus opened up the possibility of a synthesis founded, not on their subordination to mechanical conceptions, but on the free right of each to develop its own underlying assumptions in a republic of inter related universes

If there is any truth in this view, we may thank discussions like that out of which this correspondence rose for bringing it more clearly to light Its precise bearing on the particular point at issue is another matter My own amateurish suggestion was not exactly that which Sir James Jeans attributes to me I mentioned the world of values as a conspicuous example of a universe of discourse beyond the field of "pointer readings", but "values" have enough to answer for without being loaded with the problem of ether Ether might be shown to serve a purpose, to have, if we like explanatory value, and that, I suppose, is what its advocates try to show, but on that I am not competent to express an opinion

If I may restate it in other terms, perhaps less ambiguous than those I used, what I meant to suggest was, *first*, that whatever can be said for the existence of such an entity, it seems to be becoming more and more obvious that it does not fall within the universe defined as "that which is continuous with the felt, waking body", and *secondly*, that the insistence upon it nevertheless as a real entity may not be unconnected with what Meyerson calls the "natural metaphysic" of the human mind which prompts it to seek for substantiality in what it takes as "given" For, in spite of what writers like Whitehead are saying in criticism of the old category of substance, we may drive it out with a fork but it will always recur, and if there is no place for it in the universe of mathematical physics, there will always be those who will try to find one elsewhere

J H MUIRHEAD

The Use of Covers on Lambs in Biological Work on Wool

MY fellow workers on wool in the northern hemisphere will soon be welcoming a crop of lambs I should like to tell them of the usefulness of the simple device of light covers Covers for older sheep have already proved most valuable in work on the chemistry of yolk by my colleague, Mr W G Sutton The

covers provided for my lambs protect the tips of the long fibres, which otherwise have largely become broken at the age of four or five months For the classification of fibre types, it is necessary that the tips should remain intact The covers also retain the loose birthcoat kemp The kemps so far mainly studied are coarsely medullated fibres that complete their growth in a few weeks and are soon shed The coarser of these can be recognised at birth as destined to fall out, but fibres having the structural features of the finer kemps may persist, being thinner and less medullated below the point at which a shed fibre completes its growth The most satisfactory way to ascertain which fibres are shed is to hold them in the fleece by a cover By sampling at suitable times, it is then possible to compare the numbers and types of shed kemp with the numbers and types of fibres which there is reason to regard as succeeding them in the same follicles

The material that has been used is a brown proofed duck Sometimes a complete band of about eight inches has been fastened round the middle region of the sheep, sometimes only the upper half has been covered, the band being held in position by elastic bands under the belly In many cases this small cover has been protected by a larger one like a horse cover The lambs were first covered when about two months old adjustments having been made as required Up to the present time, three months after covering, the tips have been sufficiently preserved There is evidence that an extremely tight cover interferes with normal growth, but otherwise growth appears to be unaffected by covering In work on shorter kemps that have completed their growth at birth, it will be necessary to put covers on at birth

The study now in progress of the fibre types of the New Zealand Romney sheep and their development has reference especially, from the economic point of view, to the occurrence of medulla From the practical point of view, kemps are not the most important medullated fibres in this breed, but they are the first to begin to grow, and an understanding of their place in the fleece is fundamental

The work of Mr J A Fraser Roberts on kemp in the Welsh Mountain breed has been very much in mind in this investigation He has found that lambs with the same amount of birthcoat kemp may later have very different quantities of kemp The problem thus raised is also encountered in the New Zealand Romney I was much impressed by the statement, made in conversation several years ago, by Prof J E Duerden, that associated with birth there is a check upon the growth of a lamb's coat He was referring then to the form of his 'sickle fibres', with a medullated sickle shaped apical end, followed by a finger region, and he has suggested in a recent letter that the sub apical thinning found in the majority of the bigger birthcoat kemps in the New Zealand Romney may be 'birth-thinning', as he calls it This conception has come to be the guiding idea in the work now in hand In the light of this 'birth check', the structural differences displayed by the array of fibre types, that begin their growth at different times, fall simply into line Certain marked differences between individual animals in the array of fibre types are to be explained by differences in the intensity of the check at a series of corresponding stages of development Differences in the time of onset and/or in the maximum intensity of the birth check are affording a satisfying explanation of differences in the relative numbers of certain fibres, especially sickle-fibres, that are shed or continue growing I believe that an intense check causes fibres to persist that would be shed if the check were less severe In the search for the significance of various other features in the development of the coat, the principle of the birth check promises to be illuminating The birth check may well prove of interest, as an inhibiting effect, from the point of view of the physiology of heredity, but the need for an understanding of the respective parts played by genetic and non genetic factors will at once be apparent

A preliminary description of the fibre types of the New Zealand Romney hogget and their development appeared in the *Wool Record* of Oct 4, 1930 I am enjoying the benefit of discussion through the mail with the biologists that have been mentioned With the limitations inherent in work upon large, slow-breeding animals, it would be especially helpful to be in communication with any workers interested in related problems in other parts of the world It is clear that there are radical differences, apart from fibre diameter, between the South African Merino and the New Zealand Romney in the structure and development of the fibre types This fact is far from astonishing, but as the principle discovered by Prof Duerden in the Merino is proving so helpful in work on the coarser woolled breed, the importance of comparative studies is emphasised

Virulency of *Tilletia caries* on Wheat Varieties

IN a letter in NATURE of Feb 16, 1929, vol 123, p 243 I stated that certain wheat varieties thought to be resistant to bunt were susceptible when they were contaminated with the bunt spores that had been produced on those varieties It was inferred that, in the same way that the plant breeder could select a unit from a population of a variety for resistance to a certain pathogen, so the mycologist might select a pathogen from an analogous population to which the given host was susceptible

In the course of the past seven years, I have found no wheat variety that is consistently immune or very markedly resistant to this disease In the majority of the varieties studied, it was sufficient to contaminate them with their own bunt, they were then susceptible if not, they were found to be susceptible to bunt spores from other varieties—this bunt originating, so far as is known, from one source, namely, bunt that had been obtained on Little Joss wheat in 1923 For example, Hussar wheat contaminated with Little Joss spores in the season 1927–28 produced only 0 3 per cent of bunted ears, but in the succeeding season these spores were used to contaminate this same variety, and the estimated bunt percentage was then 49 It is suggested here that when traces of bunt are observed on a so called resistant variety, this fact should not be ignored, as it has been in the past It is thought this trace of bunt is a significant indication that a particular physiological form in the population of the parasite has found the given host susceptible Perpetuation of that form on the particular variety may show it to be markedly susceptible

That physiological forms of this parasite exist is shown by the following example Martin wheat appears to be resistant in England to bunt produced on Little Joss wheat, since, during the past six years, bunted ears were observed twice only, the percentages 0 5 and 0 6 were recorded on those occasions When, however, a sample of this wheat from the Cambridge plots was grown in Denmark and contaminated with indigenous bunt spores from a local

Danish variety, it produced 27 per cent of bunt Martin wheat, when contaminated with bunt spores from White Odessa grown on the University Farm, Cambridge, produced 54 per cent of bunted ears, and this White Odessa bunt had grown previously on Little Joss wheat, and the spores originated, so far as is known, from the original inoculum obtained from Little Joss wheat in 1923 It is clear, therefore, that physiological forms exist, indeed, that this pathogen is analogous to the host which it parasitises, in that it is a population from which units may be obtained

It may well be, however, that there were present naturally, on the original seeds of these varieties that were sown in 1923, a few bunt spores other than those with which I contaminated them artificially—physiological forms which would flourish in one environment and not in another

Futhermore, in their study of *T caries* many workers have undertaken very comprehensive experiments in order to determine the relative susceptibilities of wheat varieties to this parasite So much so that collections of bunt—" botanical specimens of no commercial value "—have been forwarded from country to country that their virulent nature may be determined I suggest that this is an excellent method for the commercial propagation and perpetuation of this disease—but one scarcely to be recommended in the best interests of agriculture Although no varieties are universally immune, it may well be that certain varieties are moderately resistant to certain physiological forms in certain localities, and it is with these that the plant breeder and the practical farmer are concerned It will not aid the cause of either to risk introducing foreign physiological forms

It may seem that these two opinions are contradictory for in one it is stated that no resistant varieties have been encountered, whereas, on the other hand, the opinion is expressed that it is most unwise to permit the introduction of physiological forms from one country to another, since it is to the detriment of both farmer and plant breeder In certain environments, however, it may be possible to breed varieties resistant to indigenous physiological forms of this disease which would be susceptible to forms introduced from other countries

Plant Distribution

IN the course of work on the geography of the Angiosperms, I have been impressed by the absence of any satisfactory theoretical explanation of the more general features in the distribution of these plants It will, I think, be agreed that the present distribution of the Angiosperms has been brought about by the intermingling, at different times and in different degrees, of a number of floras which have developed at different times and in different parts of the world This being so, any general theoretical explanation must provide not only a means of actual plant-movement, and a motive force for it, but also a directional control of movement and a discriminating or sifting factor

The dissemination of dispersal units obviously furnishes the means of movement, and the contemporary topographical outline and relief is clearly potent in controlling its direction As to the motive force, it is generally believed to-day that plant migration has been and is caused by change in external conditions and particularly by climatic change That is to say, change in external conditions is considered to make dispersal effective in bringing about changes in species position There is little doubt that this belief is correct, but it cannot be looked upon as an explanation of the facts of plant geography unless there is added to it some explanation as to how external change can react so as to entail species movement

It is one of the most obvious facts of plant distribution that a species can develop and maintain itself satisfactorily only within certain definite climatic and edaphic conditions, that it has, indeed, a 'range of tolerance' to external conditions In view of this, it is possible to put forward the theory that 'range of tolerance' to external conditions—or, more shortly, 'tolerance'—is a specific character, subject to variation and change in the same ways and by the same means as morphological characters

If this theory is accepted, then external change, which is itself a movement of conditions, must result in species movement, because dispersal, which is *potentially* in all directions, will be *effective* only in those directions which will maintain the spatial correlation between the species and the conditions within its range of tolerance By the same theory, the necessary sifting effect among species will follow from the differential effect of one and the same external change upon species having different tolerances

This theory of tolerance is set out and discussed at length in a forthcoming paper

Sir Isaac Newton and the Greek Philosophers

A FEW years ago I suspected that justice was not given to the brilliant astronomical discoveries of the ancient Greeks, and this led me to copy, to collect, and to classify several thousands of their passages relating to the structure and polity of the universe A sound independent basis was thus established for checking the originality of the reformers of astronomy since the sixteenth century, and for rendering "unto Cæsar the things which are Cæsar's", in a very important period of the history of science

The book of Copernicus, who had closely studied the philosophers of antiquity in their own language, broke down badly under the crucial and unanswerable test of comparison, and his heliocentric system is known to have been adopted from the Greeks without a single word of acknowledgment

In the work of the great Kepler, I came across several theories that had already been propounded by the ancients, but that founder of modern astronomy was just and generous, and ever eager to applaud the discoveries of his predecessors, so far as he could be acquainted with their writings

The treatment of the philosophers of antiquity by Newton is comparable with that of Kepler, and he did not hesitate to attribute to the Pythagoreans and to Aristarchus the discovery of the true system of the world It is a well-known fact that, in the first century of our era, Plutarch conceived universal attraction, asserting, moreover, that gravity, counterbalanced by centrifugal force, prevents the moon from falling on the earth, like a stone in a sling. As Newton does not mention the philosopher of Chæronea, he evidently never saw the passages in which these ideas had been expressed He did not understand the Greek language, and, like all great creators in science, he read little Were he to have been acquainted with the scientific works of Plutarch, he would never have failed to do him justice, as he had done, for example, to Kepler for his famous laws, or to Boulliaud for the law of inverse squares

There can, therefore, be no doubt that Newton started his inquiry by reasoning quite independently and in almost the same manner as Plutarch His splendid genius was fully equal to the task of discovering anew those eternal truths that had dawned in the mind of the Greek philosopher But there is an enormous difference between the mere conception of a scientific truth and its demonstration, and it is precisely that wonderful power of demonstration, backed, as it was, by mathematical intuition of the highest order and by an unrivalled use of induction and deduction, that has placed Newton above the men of science of all time

Paris, Feb 22

After-glow and its Life in Discharge Tubes

DURING investigations with electrical discharges through various types of tubes, I have observed some peculiarities of the after glow which appear to be worth recording It is well known that the intensity and duration of the after glow depend on the material of which the tubes are made It is also believed that the duration of the after glow ranges from a few seconds to a few minutes

While working with silica tubes filled with gases at rather low pressures, I discovered quite a strong after glow which persisted for about three quarters of an hour An after glow of such a long duration appears to be very interesting, and this fact may throw some light on the proper understanding of the mechanism of the after glow phenomenon The tubes were excited by a small induction coil giving 400 volts for its output, and the discharge was passed for two minutes During this time the tube did not show any appreciable rise in temperature This phenomenon can be repeatedly observed any number of times The after glow in silica tubes is given not only by nitrogen and metallic vapours, as is believed by some experimenters, but also it appears to be associated with almost all gases, as well as metallic vapours The glow is greenish when the current is switched off, but it soon develops into a yellowish white cloud filling the whole of the discharge tube, the density of illumination in the capillary portion being distinctly much higher than in the remaining portion of the tube

The rate of decay of this glow is extremely slow, and its intensity appears to be largely controlled by the pressure of the gas—lower pressures, ranging between 0 01 mm and 0 4 mm of mercury, being very favourable to large intensity The flash phenomenon recently recorded in NATURE (Nov 8, p 725) by Braddick is also seen in the after glows of silica tubes, but instead of there being only a few flashes before the disappearance of the glow, as observed by Braddick, the glow in the present case shows the flickering of light for quite a long time, giving an appearance something like the scintillations observed in a spinthariscope

Details of the above observations will be published elsewhere

Colours of Inorganic Salts

IN continuation of the letter published in NATURE, vol. 125, p 163, Feb 1, 1930, we wish to report that absorption spectra of vapours of chromic chloride and ferrous chloride were taken at temperatures of 1000° C to 1400° C in the vacuum furnace in order to test the theory postulated in the above communication These substances were chosen because, according to information available in standard chemical literature, they do not dissociate within the temperature range mentioned and still yield sufficient vapour for absorption work

It was found that chromic chloride yields a number of absorption bands at λ4100 A and ferrous chloride at λ4350 A These bands we ascribe to Cr^{+++} and Fe^{++}, and they are due to magnetic transitions in the d^3 and d^6 shells of these elements In addition, we obtain continuous absorption, beginning from λ3000 A and extending to the limit of our apparatus, namely, to λ2200 A We ascribe this continuous absorption to the Cl^- ion

This later conclusion is sharply at variance with the interpretation put by Franck and his students on the absorption spectra of vapours of saturated chlorides of monovalent elements like sodium and potassium, etc They observed that with these vapours absorption begins near λ2900 A, and interpreted this as indicating the photo dissociation of sodium chloride into neutral Na and neutral Cl, that is, $h\nu_a$ equals heat of dissociation of NaCl molecule, which was obtained from consideration of a Born cycle, ν_a being the frequency at which absorption begins But vapours of almost all chlorides show absorption near λ3000 A (it is not possible to locate this point with any degree of precision within 200 A units), including the vapours of magnesium, aluminium, and silicon chlorides, which show no banded absorption, and by chromic chloride vapour and ferrous chloride vapour, which show band absorption In these cases, the energy relations (correlation between $h\nu_a$ and heat of dissociation) as obtained from consideration of a Born cycle fail entirely We are therefore led to the conclusion that the continuous absorption is due to the vibration of the electron in the Cl^- ion, but whether it leads to dissociation of a kind postulated by Franck cannot yet be answered definitely

Transplantation of Portuguese Oysters into South African Waters

IT is now well known that the accidental loss of a cargo of Portuguese oysters (*O angulata*) in the Bay of Arcachon in 1866 resulted in this oyster establishing itself in the locality in a new environment Arcachon now produces hundreds of millions of *O angulata* annually The possibility of successful transplantation of this species is therefore proved If an accidental transplantation can be successful, it would appear that deliberate transplantation may be equally successful provided a careful selection of the ground be made

During a recent review of the distribution of oysters,[1] it was noted that oyster production on the South African coast appears to be infinitesimal in comparison with the apparent potentialities The hydrographical conditions of the south east coast of Natal would seem to be eminently suitable for the spawning and growth of the Portuguese oyster, a form which is absent from this region It is suggested therefore, that an experiment in the transplantation of this species might be as beneficial to South Africa as an unpremeditated one has been to France *O angulata* occurs on the north west coast of Africa and possibly more southerly, its absence from South Africa may be due to the set of the relatively cold Benguela or Antarctic current on the south-westerly shores[2] The Portuguese oyster

requires relatively warm conditions (68° F or more) for spawning and good growth, thus it is not unlikely that the general conditions intervening between the north west and the south of Africa have acted as a natural barrier to the spread of this species of oyster in a southerly direction

It is not improbable, therefore, that the artificial transplantation of the Portuguese oyster into South African waters might add a valuable economic product to that region

Whether private individuals would undertake an experimental venture of this kind is somewhat doubtful, and the Union Government would probably have to finance the experiment, at least in its early stages, if after due consideration the undertaking were considered economically promising It is possible that transplantation might be successful, but the experiment an economic failure, unless the economic factors are carefully borne in mind J H Orton

Deep Focus Earthquakes

In a report, issued by the Air Ministry and included in Nature of Feb 28 (p 320), of an earthquake which was registered at Kew Observatory on Feb 20, it was stated that the shock originated from a focus about 250 miles below the normal depth It may be of interest to explain how it was possible to obtain this information from the records of a single station

The first indication of deep focus was obtained from the comparatively feeble development of the surface waves H Jeffreys and others have pointed out that on theoretical grounds the amplitudes of surface waves should fall off very rapidly with increasing focal depth For normal earthquakes the ratio of the maximum amplitude (as it appears on a Galitzin seismogram) of the surface waves to the amplitudes of the preliminary impulses is about 10 or 20 For the disturbance in question, the ratio is only about unity It is difficult to recognise any well defined maxima on the records

The second indication is based on the results of an investigation which I have just completed and of which a detailed account will be published shortly This research has shown that for earthquakes of deep origin, additional phases may be produced by reflection at points near the epicentre To distinguish these waves from the ordinary reflected waves, PP, SS, etc, I have called them pP, sP, sS, etc The times of transit have been calculated for various depths of focus Some of these supplementary phases were recognised on the Kew records of the shock on Feb 20 and confirmed the belief that the focus was abnormally deep The estimate of the depth was obtained from the time intervals, which are as follows (P was recorded at 5 h 44 m 22 s G M T)

	Observed M	Observed S	Calculated M	Calculated S
$pP-P$	1	19	1	24
$sP-P$	2	2	2	4
$S-P$	9	19	9	20
$sP-P$	11	47	11	48

The calculated times are those corresponding to an epicentral distance of 77 5° (5370 miles) and a depth of focus of 0 06 of the earth's radius (that is, 250 miles), greater than normal

The Audibility and Lowermost Altitude of the Aurora Polaris

From his very interesting account of the various observations on the aurora borealis, Prof S Chapman[1] concludes that doubt still exists regarding the audibility and low altitude of some auroræ

On Aug 10, 1928, I was at Fort Smith on Slave River in the Canadian north west (lat 60° N), and witnessed a remarkable auroral display in the evening, about 11 P M In my notes at the time, it was likened to waving curtains illuminated by a slowly moving searchlight The day had been uncomfortably warm and the aurora was a surprise, as I had always connected it with low temperatures It was also quite different from the auroræ I had seen in Nova Scotia many years before

In the constantly changing tints of this aurora, green and, to a less extent, yellow were the most conspicuous colours Time after time these coloured streamers moved slowly across the sky, frequently almost horizontally, each one gradually slackening speed until it came to rest, and its movement was clearly accompanied by a low hissing or swishing sound like that of gas escaping from a tap under pressure The sound, too, gradually died down with slackening speed of the streamer Several of us watched this display for more than an hour We were on the deck of a small steamer at the riverside, from which the bank sloped steeply upwards for some hundreds of feet This afforded some basis for estimating the height of the aurora, and it seems certain that it could not have been greater than a fraction of a mile The fact that there was no perceptible lag between sight and sound, shows that the distance could not have been great

Finally, this aurora was in striking contrast with others which I had witnessed as a youth in Nova Scotia in winter These 'northern lights', as I remember them consisted mainly at least of white light, and were often like the streamers from searchlights projecting upwards into the sky They were sometimes accompanied by low crackling sounds, and gave the impression of being far away to the northward Thus it appears clear that there are two quite distinct types of aurora R Ruggles Gates

Faraday Relics

The Institution of Electrical Engineers and the Royal Institution are combining to commemorate, in September next, the centenary of Faraday's discovery of electromagnetic induction, and in connexion with the celebrations an exhibition is being arranged at the Albert Hall

The Royal Institution is contributing to this exhibition Faraday's original apparatus and illustrations of his experiments In addition, it is hoped to arrange at the Royal Institution itself a smaller exhibition of relics of a more personal character

The Managers of the Royal Institution would be glad to hear of personal relics, apparatus, and manuscripts of Faraday and those who possess any such objects and are willing to lend them for exhibition are asked to communicate with the General Secretary, Royal Institution, 21 Albemarle Street, W 1

Oceanographical Expedition of the *Dana*, 1928–1930 *

By Prof JOHANNES SCHMIDT, Ph D , D Sc ,
Carlsberg Laboratory, Copenhagen, Leader of the Expedition

THE DISTRIBUTION OF *NESSORHAMPHUS*, A NEW GENUS OF OCEANIC EELS

AS a biological example I may refer here to a new genus of pelagic eel which I am describing elsewhere under the name of *Nessorhamphus* [1] It is readily distinguished from other eels by the spatulate snout—so that seen from above it reminds one somewhat of the elongated beak of a duck—and the hind margin of the caudal fin, which is not rounded (Fig 4)

For several years I have known *Nessorhamphus* from the Sargasso Sea of the North Atlantic, our collections containing all stages from the egg and tiny larva up to adult specimens The larvæ are specially numerous, they occur in thousands and are thus well suited to the determination of the distribution, especially the breeding areas

During the *Dana's* voyage round the world we discovered that *Nessorhamphus* also occurs in the other oceans, in the Pacific as well as in the Indian Ocean, and the details of its distribution seem to me of so much interest that I propose to discuss them briefly here, even though the collections are not yet fully worked out In the western part of the Indian Ocean, around Madagascar, we found both larvæ and adolescent specimens of *Nessorhamphus* Closer examination showed that they stood so near *N ingolfianus* of the Sargasso Sea that they must be referred to this species, at the most, it can only be a matter of subspecific difference Comparison of the following averages of several important numerical characters in 200 larvæ from the North Atlantic and 70 from the Madagascar region proves this

Nessorhamphus ingolfianus	Total No of Myomeres	Preanal No of Myomeres	Postanal No of Myomeres	Large Blood vessel on Myomere No
North Atlantic	154 05	120 28	33 79	75 3
Indian Ocean around Madagascar	153 91	120 69	33 06	75 6

On the other hand, to the west of Sumatra, in the neighbourhood of the equator, the *Dana* obtained two adolescent specimens (in addition to larvæ) of a *Nessorhamphus* which was seen at the first glance to be different from *N ingolfianus*, and which I am introducing into ichthyological literature here under the name of *Nessorhamphus Danæ*, nov sp

The most obvious character is a deep black, well marked streak extending along the middle line ventrally from the head to somewhat past the anus (Fig 4, *B*), this streak is wanting in *N ingolfianus* *N Danæ* also differs in other characters, thus, the snout is relatively shorter and the distance between front of dorsal fin and the vent relatively longer The numerical characters also show differences The number of vertebræ in one of the specimens from Sumatra was found to be 137 (corresponding to 138 myomeres in the larval stage), whereas in 100 larvæ from a station in the Sargasso Sea the myomere numbers varied from 150 to 159, and in 65 specimens from the Madagascar region from 149 to 158

In the Indian Ocean we found *Nessorhamphus Danæ* not only west of Sumatra but also on both sides of the equator farther west, in the waters between the Maldives and Seychelles, and in specimens from the equatorial parts of the Indian Ocean the number of myomeres varied between 135 and 145, thus showing a range of variation similar to that of *Nessorhamphus ingolfianus* in the Sargasso Sea and round Madagascar

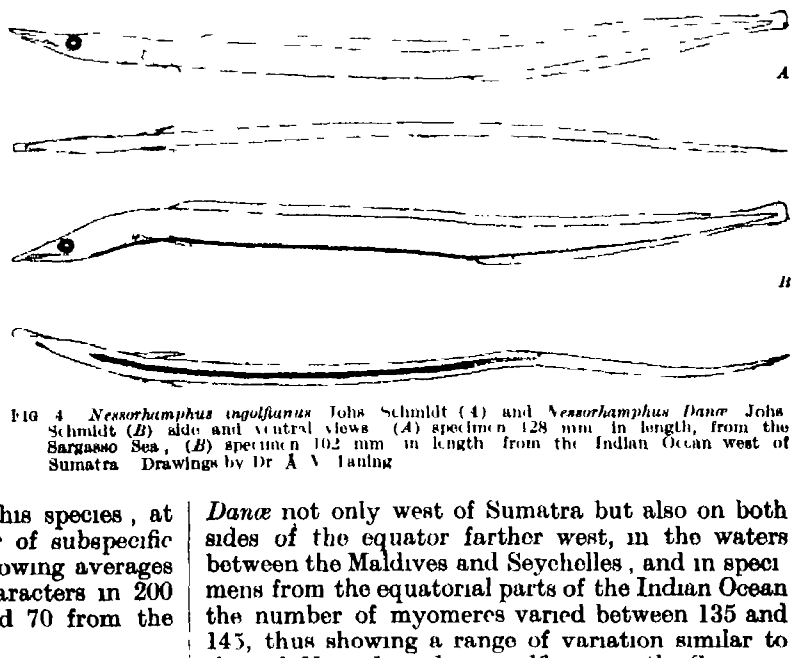

FIG 4 *Nessorhamphus ingolfianus* Johs Schmidt (*A*) and *Nessorhamphus Danæ* Johs Schmidt (*B*) side and ventral views (*A*) specimen 128 mm in length, from the Sargasso Sea, (*B*) specimen 102 mm in length from the Indian Ocean west of Sumatra Drawings by Dr Å V Tåning

In the Pacific we found *Nessorhamphus Danæ* in the equatorial belt north of New Guinea and Celebes, etc , the number of myomeres varying here between 136 and 145 † *Nessorhamphus* also proved to occur in the south Pacific along the whole stretch from the Marquesas to New Caledonia and the north-western part of the Tasman Sea, but this was not *N Danæ* It was a form which approaches *N ingolfianus*, both in its high number of vertebræ and the absence of the ventral streak which characterises *N Danæ* ‡

Turning now to the third ocean, the Atlantic, no specimens of *Nessorhamphus* were found by

* Continued from p 448.

† For twenty-seven specimens the averages corresponding to those given in the previous table were 140 37—112 19—28 10—72 04

‡ The number of myomeres varied in six specimens from 152 to 162, but in such a small number of specimens this is such a wide range that possibly a mixture of two forms is present

the *Dana* in the southern portion, from the Cape towards Ascension, but in the neighbourhood of the Line, on both sides of this, a few larval specimens were found which proved to belong to *Nessorhamphus Danæ*, with the number of myomeres varying from 135 to 145

The distribution of the genus *Nessorhamphus* is summarised in the accompanying chart, Fig 5 This is based on the occurrence of larvæ and thus represents the breeding regions As in all eel fishes, these are restricted to the warmer parts of the oceans For the rest, the most characteristic features of the distribution may be summed up as follows

1 Both main species, *Nessorhamphus Danæ* and graphical conditions also recall to some extent those of the Sargasso Sea I have not much doubt that *N ingolfianus* extends from Madagascar across towards Australia, and that *N Danæ* occurs from New Guinea far to the east in the equatorial belt

From our investigations of the home fishes we know what great importance the hydrography, and especially the temperature, has in the distribution of the different species, more especially at spawning time In 1909 I illustrated this in the case of the North Atlantic species of Gadoids, and demonstrated that it is the varying temperature requirements in the different species during the spawning period, when the species are specially sensitive, which determines the situation of the spawning

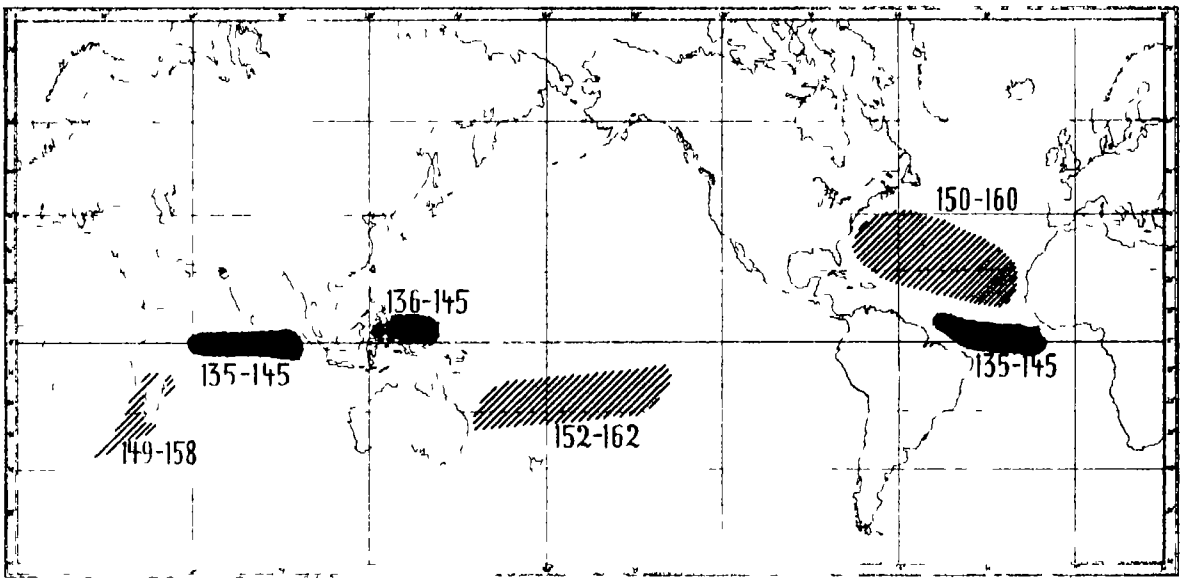

FIG 5 Distribution of the larvæ of *Nessorhamphus ingolfianus* Johs Schmidt shaded and of *Nessorhamphus Danæ*, Johs Schmidt black (each including subspecies or races) The figures denote number of myomeres

N ingolfianus (each including subspecies or races) occur and spawn in all three oceans

2 In each of the oceans the two species are distributed in the same manner, with regard to latitude, as in the other two oceans Thus, *Nessorhamphus Danæ* occurs in a belt about the equator, whereas *N ingolfianus* is found about the transitional circles, both on the northern and southern hemispheres We may call this type of distribution the latitudinal

This is the actual distribution of the genus *Nessorhamphus* so far as the *Dana's* investigations go Large regions of the oceans, however, in the North Pacific and South Atlantic for example, must be investigated before the picture is complete It would not be remarkable if it proved that the transitional region of the North Pacific contained a fish belonging to the form-series of *N ingolfianus*, or at any rate to a related species, for the hydrographical conditions there, at least in the western part, greatly resemble those of the Sargasso Sea One must similarly take into account the South Atlantic in the neighbourhood of the transitional circle, especially its western part, where the hydrographical grounds and thus right away the distribution of the different species [2] Also, there can be no doubt that in the case of the oceanic fishes it is also the hydrography—making allowances for the historic factors—which determines the breeding areas of the species and thus in the first case their distribution

Now, large and characteristic differences actually occur between the equatorial zones and the zones about the transitional circles in hydrographical characters, both in the upper and intermediate water layers, where the propagation and larval development of *Nessorhamphus* take place This applies to the temperature, salinity, oxygen contents, etc , and it cannot be doubted that such differences, in conjunction with specific demands on the environmental conditions, determine the spawning regions and distribution of the two *Nessorhamphus* species

The further examination of the *Dana* material will presumably bring to light types of distribution other than the latitudinal, as in *Nessorhamphus* , but this will undoubtedly be found again in many other cases, possibly with even greater clearness in other cosmopolitan genera of oceanic fishes,

especially in those which contain several main species, and, in contrast to the eel fishes, are not restricted to the warm zones but also occur and spawn in regions of lower temperatures

The above information regarding *Nessorhamphus* may be taken as a first example of what may be reached from two months' work, dealing with the *Dana* material from the point of view outlined in the beginning—that is, by using biometric methods and including the large larval material Without the latter, from the study alone of the quite few adult specimens available, we should not have understood in the least the peculiar features of the distribution of the genus Even if a great deal is still wanting, it is certainly not a common thing in natural history, along with the description of a new genus, to be able to give so much regarding the distribution of its species

OXYGEN IN THE TROPICAL PACIFIC

By HELGE THOMSEN, Hydrographer of the Expedition

On the 1921-22 expedition with the Royal Danish Research Ship *Dana* the remarkable fact was discovered, at several stations in and close to the Gulf of Panama, that the sea water contained practically no oxygen at a depth of *c* 400 m, but at that time there was no opportunity of following up the horizontal distribution of this phenomenon[3] As the projected course of the *Dana* in its world cruise in September 1928 lay across the Pacific from Panama to New Caledonia, one of the principal hydrographical aims of the expedition, as planned by its leader, was the investigation of the minimum distribution of oxygen towards the west

The result of these investigations, which were undertaken in the months of September, October, and November 1928, is displayed in Fig 6, which shows the oxygen distribution in a section from Panama to the south point of New Caledonia, the position being given on the route chart, Fig 2 The figures on the curves denote the percentage of oxygen observed, compared with the quantity of oxygen which would be found in the water if it were saturated with oxygen The smallest quantity was found in the Gulf of Panama at a depth of 400 m and amounted to 0 03 c c of oxygen per litre of sea water, corresponding to 0 5 per cent saturation This minimum extends westwards from the Gulf of Panama, always with nucleus about 400 500 m, but with steadily rising amount of oxygen As far as long 125° W the minimum value still remains less than 10 per cent, and up to *c* long 140° W less than 20 per cent, but about long 148° W, that is, near Tahiti, the minimum ceases to be apparent in the saturation percentage

Consideration of the section shows, further, that

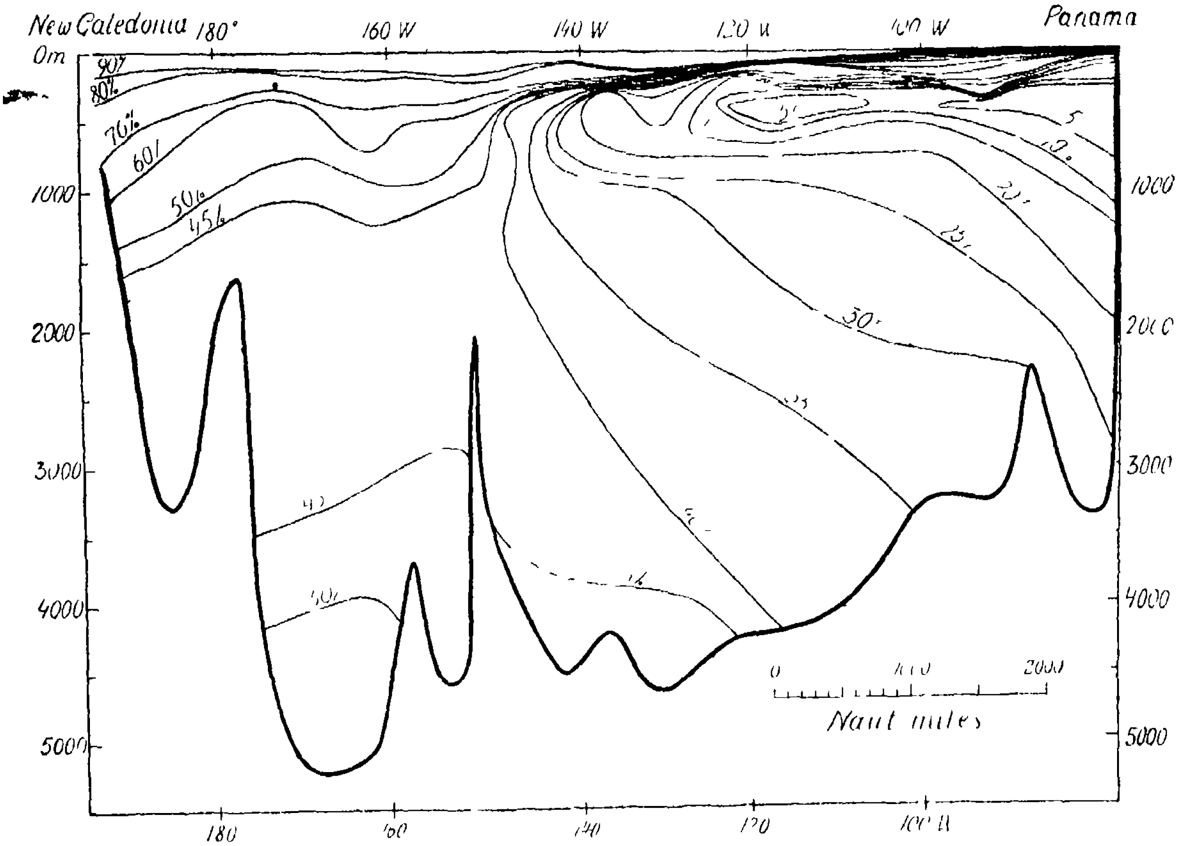

FIG 6—Section of the ocean from Panama to New Caledonia showing distribution of oxygen

it may be divided naturally into two portions with the boundary about Tahiti In the eastern portion the amount of oxygen diminishes very rapidly with the depth down to the minimum at 400 500 m , thereafter increasing again towards the bottom, where increasingly higher values are obtained the farther one goes westwards

On the other hand, in the western portion of the section we find a slower decrease in the amount of oxygen with the depth, until a minimum is reached at *c* 2000 2500 m , after which it again increases gradually towards the bottom This minimum, however, is not nearly so well marked as the minimum in the eastern portion, the saturation percentage not going below 40 per cent Thus, whilst the saturation percentage in the western portion is everywhere greater than 40 per cent, throughout the eastern portion it is less, with the exception of a surface layer of small extent and the bottom water in the part of the section which lies west of long 120° W

These conditions agree well with what one might have expected beforehand In tropical seas, with high temperature and relatively low salinity at the surface, the density of the surface water will be so much less than that of the layers below that the descent of oxygen to the latter by vertical convection currents cannot take place An addition of oxygen to the deeper layers in the equatorial zone must therefore come from meridional currents, which will be deflected westwards with the earth's rotation and thus come to have a stronger influence in the western than in the eastern portion of the ocean Hence the supply of oxygen will be greatest in the western portion, in agreement with the above section

It may be noted, however, that this section does not follow the same degree of latitude, extending as it does from lat 7° N in the eastern portion to lat 23½° S in the western portion If the indicated supply of oxygen to the equatorial zone takes place from the south, as the available hydrographical data suggest, this in itself would cause the western portion of the section to contain more oxygen than the eastern portion, and we should expect that a section due west from the Gulf of Panama would contain less oxygen than the foregoing Other observations indicate that this view is very probable For example, the American Carnegie Expedition, working in these waters a year after the *Dana* found an oxygen minimum of 0 5 to 1 per cent in depths between 100 m and 400 m at *c* lat 12° N and long 137° W [4] This minimum is of the same dimension as that found by the *Dana* expedition at Panama and considerably less than the minimum measured by the *Dana* on the same degree of longitude but some twenty degrees more to the south

In July 1929, when the *Dana* expedition was working in the waters north of New Guinea, an oxygen minimum of 27 3 per cent was found in 400 m at lat 3° 40′ N and long 137° 40′ E These observations afford strong support to the view that the layer poor in oxygen, which was first noticed by the *Dana* in 1922 in the Gulf of Panama, is centred about lat 5° to 10° N and extends at a depth of about 400 m right across the whole Pacific, though the minimum becomes less marked the farther we go westwards, yet still about 27 per cent in the westernmost part It is worth remarking that this oxygen minimum has about the same geographical distribution as the equatorial countercurrent The existence of the very poor oxygen layer under the latter shows that in these depths the currents with a meridional component must be extremely weak

In conclusion it may be mentioned that a somewhat similar oxygen distribution was found in the tropical part of the Atlantic in 1926 by the German *Meteor* Expedition,[5] and, though less strongly marked, in 1921 by the *Dana* along a section from Cape Verde Islands to Cayenne [6] Further, an intermediate oxygen minimum was found by the *Dana* in the tropical Indian Ocean during the Circumnavigation Expedition in 1929 There seems to be no doubt, therefore, than an intermediate oxygen minimum extends as a belt round the globe in the equatorial zone

The Nature and Scope of Physical Science *

I

By Prof HERBERT DINGLE

SCIENCE may be defined as the recording, augmentation, and rational correlation of those elements of our experience which are actually or potentially common to all normal people The phrase cannot boast of elegance, but for clear thinking, rigidity and conciseness are the important considerations

To prevent excessive misunderstanding, some explanations are necessary, which limits of space compress to the barest minimum By 'experience' is meant everything of which we are conscious except rational conceptions Experiences 'common to all normal people' may for practical purposes be thought of as observations made by means of the senses, but since what fits them for scientific discussion is not the way in which we get them

* Substance of a course of four lectures delivered at the Royal Institution on Jan 22, 29 Feb 5 and 12

but the fact that they are universal, the more general description is preferable By expressing the data of science as experiences and not as the external world giving rise to them, we evade the problem of the objectivity of that world, that is a problem for philosophy, not for science Finally, the word ' potentially ' is inserted in the definition merely to include observations which might be made but are not, it is not a loophole for the admission of *hypothetical experiences* which *future* developments of the human organism might make possible

The definition limits science only in respect to its data and its purposes, it imposes no limitation on method As a historical fact, of course, science has almost invariably restricted itself to the familiar processes of observation and experiment for the accumulation of its data, and to abstraction and hypothesis for their rational correlation It is conceivable, however, that science might be advanced by other means, for example, clairvoyance, but if such means are employed, their indications must always be confirmed by common observation before they are accepted as a part of science

Nevertheless, in the history of science, the methods of abstraction and hypothesis have been of the utmost importance, and the significance of physics at the present day has, I think, been widely misunderstood through a misapprehension of their essential nature Let us look at them a little more closely

Abstraction is the detection of a common quality in the characteristics of a number of diverse observations, it is the method supremely exemplified in the work of Newton and Einstein Newton, for example, gave us ' laws of motion ' Now, motion is not an experience, what we observe are moving bodies Motion is an abstraction, a quality conceived to be possessed by all moving bodies, however much they may differ in size, shape, colour, beauty, virtue, or anything else The laws of motion express the characteristics of this common quality, and they are therefore a rational means of correlating a vast body of common experience

A hypothesis serves the same purpose, but in a different way It relates apparently diverse experiences, not by directly detecting a common quality in the experiences themselves, but by inventing a fictitious substance or process or idea, in terms of which the experiences can be expressed A hypothesis, in brief, correlates observations by adding something to them, while abstraction achieves the same end by subtracting something For example, to correlate the motion of Uranus with that of the other planets by abstraction in the year 1845 would have been a terrifying business The simpler plan was adopted of supposing the existence of another planet which, with Uranus, obeyed the laws of motion abstracted from the behaviour of the more familiar planets, and the problem was solved

A hypothesis of this kind can be " proved to be true " That is, of course, what occurred in the example just given, which led directly to the discovery of the planet Neptune But there are other hypotheses which cannot be thus verified, for example, the supposed birth of the planets through the influence of a passing star This is not the only, nor at the moment the most conspicuous, type of unverifiable hypothesis, but we shall return to this point later

The mental processes involved in abstraction and the formulation of hypotheses can be traced back through the ages At the beginning of modern physics, however, only the method of abstraction was employed Newton was the sworn foe of hypotheses The elements of his philosophy —mass, force, absolute space and time—were abstractions from observations, in terms of which the processes of the physical world were described He always strenuously opposed the imputation that he employed hypotheses, and although nowadays it is commonly stated that gravitation, for example, is a hypothesis, it could be shown, if space permitted, that it expresses nothing more than is actually contained in observation, that is, it is an abstraction The same method has now been applied to a more extensive field of observation by Einstein, and the theory of relativity is a pure abstraction after Newton's own heart The equations of the electro magnetic field, the principle of the conservation of energy, and the second law of thermodynamics are other examples of abstraction in physics

The great influence of Newton dominated the activities of physicists and mathematicians during the eighteenth century, and the progress of that time is summed up partly in the successful application of his principles to detailed phenomena and partly in the reformulation of his essential ideas into alternative expressions more convenient for certain calculations Hypotheses were at a discount But, fortunately for science, other influences were independently at work which, so far as physical science is concerned, found the most effective medium of operation in chemistry Chemistry, no less than physics, had throughout the Middle Ages been held back by the arbitrary adoption of ' principles ' and ' occult qualities ', but it had suffered no martyrdom such as had canonised physics and astronomy in the person of Galileo It had therefore no need of a formal body of doctrine, and while it could profit by the purifying influence of the great physicists, it could also regard with tolerance what to them was heresy Consequently we find chemistry freeing itself from superstition more gradually than physics, but at a smaller cost Thus, while Newton was declaiming against hypotheses, Stahl was conjuring up the spirit of phlogiston which was to direct chemical progress for the next hundred years This freedom of chemistry to be influenced, but not controlled, by the mathematical revolution is of the utmost importance, for by the gradual merging of the two sciences into one, physics has slowly become emancipated from the restrictions which Newton imposed, although whether she has done so without sacrificing the principles for the sake of which he imposed them is a matter of grave doubt

I have neither space nor knowledge to trace in detail the introduction of hypotheses into physics

To illustrate the process, however, here are three quotations from representative men of science, covering the period from Newton to the present time and separated by roughly equal intervals The first is from Newton himself (1687) "I frame no hypotheses For whatever is not deduc'd from the phænomena, is to be called an hypothesis, and hypotheses, whether metaphysical or physical, whether of occult qualities or mechanical, have no place in experimental philosophy" The second is from Laplace (1796) "I will suggest an hypothesis which appears to me to result with a great degree of probability, from the preceding phenomena, which, however I present with that diffidence, which ought always to attach to whatever is not the result of observation and computation" The third is from Eddington (1926) "Care is taken to provide 'macroscopic' equations for the human scale of appreciation of phenomena as well as 'microscopic' equations for the microbe But there is a difference in the attitude of the physicist towards these results, for him the macroscopic equations—the large scale results—are just useful tools for scientific and practical progress, the microscopic view contains the real truth as to what is actually occurring" The direction of development is obvious, and its validity is the most vital question, both for the philosophy of science and for the application of scientific ideas to other departments of thought, at the present time

The introduction of the atomic hypothesis into physics raises the question of the significance to be ascribed to hypotheses which postulate entities (such as atoms and electrons) which are essentially unobservable I think the conclusion is inescapable that such entities can be regarded only as concepts, possessing no properties and subject to no laws other than those which are necessary and sufficient to enable them to correlate observations The question whether they are *real* or not is already answered in the designation of them, for we can scarcely regard anything as real, in the sense in which observed existences are real, which is essentially unobservable If we adopt such hypotheses, therefore, we have perfect freedom to shape them as we please, provided they achieve the end for which they were created We are not bound to give them the characteristics of phenomena They are employed for rational correlation and are not admissible to experience they must therefore have rational properties, but not necessarily sensible ones

This, however, was overlooked by the physicists of the early twentieth century, who appeared to be faced by an irresolvable dilemma in the inability of the atom to emit radiation without self-destruction The position was that either the solar system model of the atom, to which the development of the atomic hypothesis had apparently inevitably led, or the laws of electro-magnetism, abstracted from phenomena, had to be left out of consideration if the atomic hypothesis was to be extended to include the interaction of matter with radiation, and physicists in general were willing to abandon neither Why was this?

It was simply that they did not realise the essential character of a hypothesis The atoms, being hypothetical units, were in their hands to mould to the dictates of their imaginations, and they did not know their own freedom They thought of atoms, not as hypotheses but as potential phenomena and therefore necessarily subject to the laws already established for phenomena by the method of abstraction The process began when atoms were first introduced into physics At that time they were supplied instinctively with mass and the other Newtonian abstracted qualities, and the implication that they were potential phenomena took such hold of succeeding physicists that by the twentieth century its arbitrariness needed a genius to perceive it Fortunately the genius, in the person of Neils Bohr, was at hand Bohr retained the solar system model of the atom, but absolved it from obedience to the laws of electromagnetism

This step of Bohr's was the most significant in physical science since the introduction of the hypothesis of atoms What virtually it did was to establish the fact that the hypothetical atoms were pure conceptions that they belonged essentially to a different category from the facts of observation They were creatures of the imagination, to be formed into the image of our fancies and restricted by whatever laws we cared to prescribe, provided only that when they behaved in accordance with those laws they should reproduce phenomena They were removed from the realm of experience and deposited in that of reason

Developments have succeeded one another with almost alarming rapidity, but from the fundamental point of view nothing new has happened The solar system model has gone and a conception devoid of any pictorial aspect has taken its place, but that—if in so speaking we may disclaim any disrespect to the brilliant physicists who have organised the process—is but the ass's kick at the dead lion Whatever formal doctrine physicists may profess, they exhibit in practice no more belief in the phenomenal reality of atoms than in the philosopher's stone

News and Views.

The Duddell Medal for 1930 of the Physical Society was presented to Sir Ambrose Fleming at the annual general meeting of the Society on Mar 20 The medal is awarded not more frequently than once a year to persons who have contributed to the advancement of knowledge by the invention or design of scientific instruments or by the discovery of materials used in their construction Sir Ambrose Fleming's connexion with the Physical Society dates back to its very beginning, for he read the first paper at the inaugural meeting of the Society in March 1874 In 1879, Sir Ambrose designed a special form of resistance balance for comparing standard coils, and a special form of standard coil capable of taking up

more quickly the temperature of the water in which it was placed than the form before in use When practical incandescent electric lighting began, and quick and accurate workshop methods of electrical measurement became necessary, he made, in 1883, the first direct reading potentiometer set to read directly current and potential in amperes and volts by means of a standard Clark or Weston cell Sir Ambrose also designed a form of wattmeter, with which he made extensive researches on alternating current transformer efficiencies, reported to the Institution of Electrical Engineers in 1892 In this paper he first suggested the use of the term 'power factor', which at once came into everyday use

WHEN practical wireless telegraphy first began under Marconi in 1898, no appliances were obtainable for measuring wave lengths and frequencies In 1904, Sir Ambrose Fleming invented his cymometer, which provided a simple instrument for this purpose, capable also of measuring decrements and small capacities and inductances, and, in conjunction with Prof Clinton, he also devised a rotating commutator for measuring the capacity of aerial waves and Leyden jars used in wireless In 1904, he invented his now famous two electrode thermionic valve, which prepared the way for the subsequent improvement of the three electrode valve which is now the master weapon of the radio engineer Between 1892 and 1895 he carried out, in conjunction with the late Sir James Dewar, extensive researches on the electric and magnetic properties of matter at low temperatures, and devised for this purpose special forms of resistance coil, condenser, and bridge and potentiometer for the measurement of resistances, inductive capacities, and thermo-electromotive force He was the first to establish a laboratory for high frequency and radio measurements, at University College, London, where he was professor of electrical engineering for forty two years

THE British Science Guild has submitted to the Royal Commission on the Civil Service a memorandum upon the structure and organisation of the Civil Service, dealing with what it describes as a "national imperfection" The Guild points out that in many present day problems confronting Government Departments the technical and scientific aspects are of paramount importance, and it is therefore essential that an officer of the 'expert' class should be given the fullest opportunity of advancing his views and opinions, if necessary, in the presence of the ultimate authority, namely, the Minister It accordingly advocates the development of the board system as it obtains in the larger and more progressive industrial undertakings At the same time, the Guild states that it is necessary, in order to attract men of first rate scientific and technical ability to the Civil Service, that "steps should be taken to remove the idea that the status of the officers performing scientific and technical duties in the Civil Service is inferior to that of the administrative and clerical groups"

THE heads of the larger and more important professional, scientific, and technical departments of the Civil Service should the British Science Guild claims, be given the status accorded to the highest administrative officers The Guild doubtless has in mind the fact that whereas there are some thirty 'administrative' posts carrying a salary of £3000 per annum and a greater number with a salary of £2200, there are only some three or four posts on the professional or scientific side with a salary of as much as £2500, the remainder receiving in every case less than £2000 The Guild further maintains that the fact that an officer with administrative gifts happens to be a professional man should not in practice debar him from administrative preferment Finally, it is urged that the time is ripe for a simplified structure for the technical services—using that term in the broadest sense—based on their essential underlying unity, namely the discovery and application of scientific principles for the good of the community and the increased efficiency of the services administered by the State, and in this connexion, reference is made to the proposals for such a simplification which have been put forward by a Canadian Royal Commission for the assimilation to seven grades of an 'unnecessarily cumbrous" structure of 203 separate professional, scientific, and technical grades

THE Commission appointed by Congregation in March 1930, to advise the University of Oxford as to the best method of securing such library provision as shall be abreast of modern requirements, has issued its report The report is marked "confidential", but its principal contents are matters of common knowledge, and are now being freely discussed The only portion of the report that directly affects the scientific interests of the University is that dealing with the present condition and future development of the Radcliffe Science Library, now housed within the precincts of the Museum The building known as the Radcliffe Camera was the first home of the scientific and medical library provided and maintained under the bequest of Dr John Radcliffe in the early days of the eighteenth century In 1860, the scientific and medical books were removed, with the consent of the Radcliffe Trustees, to quarters in the recently established Museum in the Parks, here they remained until in 1901 the present building the gift of the Drapers' Company, was completed and ready to receive them Since 1927, the Science Library has become the property of the University it is administered by the Bodleian Curators, the Radcliffe Trustees contributing £1500 a year towards its maintenance The Commission reports that the present system is well adapted to the needs of workers in science, but it is considered that further accommodation for books and staff is essential A prolongation towards Parks Road and northward along it is recommended, the extended building being roughly L shaped

THE British Arctic Air Route expedition in Greenland has sent a note, published in the *Times* of Mar 18, on its plans for exploration during the coming summer One of the aeroplanes is badly damaged and the other requires some repairs, but both will be available to relieve the party on the interior ice cap and to support

a party that is to explore the coast regions to the north of the base on Sermilik fjord This party set out with dog teams on Mar 14 to map the inland edge of the ice free margin of the coast between Sermilik fjord and Kangerdlugsuak fjord They are travelling on the edge of the ice cap and hope to explore a lofty mountainous area which the expedition sighted last year, at the head of the last named fjord This is approximately the region named Schweizer Land by Quervain in 1912 It contains at least one peak more than 11,000 ft in height The coast of this stretch of land was mapped in detail last summer A second party is to move south from the base, mapping the coast, which is little known, for about a hundred and fifty miles This party will travel relatively easily over the sea ice and obtain plenty of food from seals Sermilik fjord is also to be re surveyed Thus the entire expedition will be in the field during the spring and summer months Mr H G Watkins, the leader, believes that if an air route over Greenland to Canada proves feasible, it will cross the east coast between Angmagssalik and Kangerdlugsuak fjord

ON Mar 18, the Symons Memorial Lecture was delivered before the Royal Meteorological Society by Comdr E C Shankland, his subject being "Navigation from the Viking Period to the Present Day in relation to Science and Meteorology" Comdr Shankland sketched the probable ideas which lay at the back of the Vikings' schemes for voyaging first westward then south westward, and finally making voyages of more than 2000 miles The information of climatic conditions existing in the ninth century which we possess from reference to early literature provides an interesting possibility that there was an extremely dry period for several years As without precipitation there can be no surface moisture and consequently ice, the presumption that many parts of north Europe, such as Greenland, now perennially ice covered, were dry and open for exploration, may have induced the Vikings to venture afield to some remote places overseas So much of the world's navigation history has been made and adventure commenced in the North Atlantic (either from the British Isles, Scandinavian, or Continental seaports), that the use of an elementary sextant to maintain the measurement of latitude by the polar star was, in Comdr Shankland's opinion, used prior to the compass or lodestone in Europe Cargoes carried by ships are the product of the land, and any port enjoying trading facilities and relations with the more habitable portions of the earth must be at an advantage if centrally situated The want of local knowledge of the weather in the North Sea and Irish Sea was probably the greatest meteorological event in our history, as it contributed towards the loss of the Spanish Armada and so gave Britain the freedom of the seas Among modern practices, the wind pressure on ships, and the utility of the barometer in gauging the lifting power of salvage pumps in salvage operations, were explained

WITH the current issue for March, *Antiquity* enters upon the fifth year of its existence Those who are responsible for its publication have earned congratulation and deserve every support *Antiquity* has shown that it is possible to maintain a high level of scientific interest with a style and form which will appeal to the average educated reader In the current number, the editor takes advantage of the fact that his editorial notes are written in an oasis of southern Tunisia to discuss the possible relation of the type of dwelling of the troglodytes of the Matmata hills, twenty seven miles south of Gabes, of which the unit is the single cave room, with the cave dwellers of palæolithic times and the megalithic temples of Malta Mr Crawford contributes an article on "Historical Cycles", and Prof Elliot Smith deals with the discovery of primitive man in China Prof Gordon Childe reviews the results of four years' excavation at Skara Brae, Orkney, for which he inclines to a Bronze Age date Mr Stuart Piggott discusses the possible origin of the Uffington White horse, on the basis of an interesting comparison with the horse design of early Iron Age coinage Mr C Hawkes's paper on hill forts, based on evidence from such as have been examined, is a pregnant study of distribution, which illustrates both by its inclusions and its omissions the comments in our issue of Mar 21, p 429, on the need of an archæological survey in Great Britain and co ordination and co operation in future research

SINCE 1874 the State of Illinois, U S A, has carried on a State Laboratory of Natural History, which in 1917 became merged with the State Entomologist's Office, to form the Natural History Survey Division Many valuable papers have been published by the workers of the Survey and their predecessors, dealing in large part with the systematic characters of different groups in the fauna of the State But more general papers, discussing, for example, the ecology of various types of country, have also appeared frequently in the series, and it is interesting to see that so long ago as 1880, Stephen A Forbes, the present chief of the Survey, was writing "on some interactions of organisms", on the food of birds, on insectivorous beetles, and still earlier on the crustacea eaten by fishes Since 1876, the *Bulletin* has been published, and now the Survey publishes a 29-page pamphlet containing a "Classified List of Publications", in which the titles of all papers and reports not out of print are arranged under subject and author headings The endeavour of the State in publishing its reports is to increase and spread the knowledge of the plant and animal life of Illinois, and, with this end in view, the Survey is prepared to distribute its papers, so far as reprints are available, to organisations and individuals willing to use them to stimulate further interest in natural history as a feature of public education Those interested should apply for the Classified List of Publications to the Chief, State Natural History Survey, Urbana, Illinois

THE Lane Lectures on Experimental Pharmacology and Medicine for 1927 were to have been given by Prof Rudolf Magnus, of the University of Utrecht, but his untimely death that year prevented the fulfilment of this plan Three of the five lectures con-

templated had, however, been completed, and these are now published under the editorship of Prof P J Hanzlik in the Publications of Stanford University, California (Medical Sciences, vol 2, No 3 1930) The lectures are entitled "A Contribution to the Experimental Pathology of the Lungs", "Choline as an Intestinal Hormone", and "The Physiological 'A priori'", and deal with certain aspects of physiology in which Prof. Magnus was interested and had carried out investigations The monograph, however, contains, in addition, a biographical note by Dr H H Dale and a list of Prof Magnus's works, compiled by Dr A de Kleijn, which considerably enhance its value Prof Magnus will be remembered chiefly for two investigations the first, carried out at Heidelberg, showed that the smooth muscle coats of the intestine retained their vitality and many of their activities when the organ was suspended in warm oxygenated Ringer Locke solution the second, carried out at Utrecht and occupying the greater part of his eighteen years at this University, on the factors controlling the changes of animal posture This work was published a few years ago in the great monograph, "Körperstellung" But the bibliography shows that his interest in pharmacological problems continued throughout, and in fact two of them formed the subject of the Lane lectures

THE diagnostic and therapeutic uses of the applications of electricity in medicine and surgery are continually growing in value It is only recently that any attempt has been made to rationalise the electrical apparatus used in accordance with electrical engineering standards We consider, therefore, that the paper on the medical and surgical application of electricity read by Dr Bernard Leggatt to various centres of the Institution of Electrical Engineers and published in the February *Journal* will prove very helpful He considers that the great value of this branch of electricity is not generally recognised in Great Britain In the diagnosis of disease, the combined services of the pathologist and radiologist are responsible for about 95 per cent of all positive diagnoses, hence it is surprising that on most hospital staffs these two specialists are not considered of sufficient importance to have seats on the hospital medical committee The applications of X rays, which present the widest field at present both for diagnosis and the treatment of specific diseases, are discussed at length Great differences of opinion exist as to the relative value of gas and electron X ray tubes These differences are easily explicable, when we consider the physics of the problem Any dangerous electrical apparatus can be installed in a hospital without supervision and operated by persons entirely ignorant of electricity, as, unlike workshops and factories, there are no Home Office regulations applicable The best methods of producing ultra-violet radiation and of measuring its dosage are described The use of high frequency currents to heat the tissues of the body to any desired degree is favourably commented on, and also the uses of the electrocardiograph Some of the electrical treatments which have been suggested and are sometimes employed are of questionable value

THE Report on the Investigation of Atmospheric Pollution in the year ending Mar 31, 1930, issued by the Department of Scientific and Industrial Research, is a quarto pamphlet of 74 pages and costs 4s (London H M Stationery Office) According to it, the average amount of solid matter washed out of the atmosphere by the rain, at the 70 stations where observations are made, is slightly less than last year, but at 5 of them (in Burnley, Liverpool, Newcastle on Tyne, Rochdale, and Rotherham) it still exceeds 760 tons per square mile per annum, while very few get less than 100 tons per square mile per annum When there is no rain to wash it out, this matter is present in the atmosphere at the rate of 1 or 2 milligrams per cubic metre of air, and may be carried down the wind for many miles In London and Glasgow, domestic fires account on the average for 75 per cent and industries for 25 per cent of this solid material While in the air, it obstructs the passage of light and particularly of ultra-violet light, and the observations at Rochdale show that 29 per cent of the ultra violet light which reaches the outskirts of the town, where the pollution is less, is lost at the centre of the town, where the pollution is greater

A CHEMICAL library of historic interest has just been discovered in the Bodleian Library by Dr R T Gunther, who has published a list of twenty three of the books in the recent issue of the *Bodleian Quarterly Record* The greater number of the volumes now described were given, in 1683, by various benefactors to form the nucleus of a departmental library when the Ashmolean Chemical Laboratory was opened, as described in NATURE for April 2, 1927 The existence of this venerable collection of books, the oldest public chemical library in Britain, had long been forgotten owing to loss and dispersal of its volumes to fill gaps in the series of Ashmolean manuscripts, with which it had nothing to do Fortunately, the names of donors have been inscribed in several of the books, thus establishing their identify The more important gifts came from the vice chancellor, the dean and other members of Christ Church, from Dr Plot the first professor of chemistry, and from John Cross, the 'privileged' apothecary at whose premises, in the Oxford High Street, Boyle and Hooke conducted their epoch making researches in 'pneumaticks' None of the books is recorded as having been presented by Ashmole, although he was the founder of the professorship of chemistry

IN connexion with the total solar eclipse on Aug 31, 1932, which will be visible in Canada and the United States of America, it is hoped to organise two tours from Great Britain Tour 'A' will leave on or about July 22, and, after landing at Montreal, will proceed to Victoria, B C, by the Canadian Pacific Railway The return journey will be through North America, arriving at Boston on or about Aug 30 All the more important observatories will be visited Tour 'B'

will leave on or about Aug 12, and will not be such an extensive one, but will arrive at Boston about the same time as tour 'A' A joint attraction is the meeting of the International Astronomical Union under the presidency of Sir Frank Dyson, the Astronomer Royal, which will be held at Harvard as soon after the eclipse as possible Members of either tour may have their ocean tickets made available for return directly after the eclipse or after the meeting of the I A U Further information may be obtained from the Assistant Secretary, Royal Astronomical Society, Burlington House London W 1

THE tenth anniversary of the founding of the first birth control clinic by Dr Marie Stopes was celebrated by a dinner at the Ritz Hotel on Mar 17, when a distinguished company assembled to congratulate her upon the success of her campaign Since the opening of the clinic direct personal instruction has been given through lady doctors and midwives to more than twelve thousand cases, mostly very poor women, who have attended for advice and help Travelling clinics have been initiated which have done valuable service in South Wales and the industrial north It is important to remember that Dr Marie Stopes' society exists for "constructive birth control", and that therefore it is concerned with the positive control of conception and the production of desired children as well as the prevention of childbirth by contraceptive methods Information as to membership may be obtained from the Secretary, C B C 108 Whitfield Street, London, W 1

AN earthquake of moderate intensity was recorded at Kew Observatory at 8 h 16 m 38 s G M T on Mar 18 The epicentre is estimated to have been 7340 miles away The readings obtained at Kew, Fordham (North America), and Pasadena indicate that the epicentre of the shock was near lat 34° S, long 71° W, that is, near Santiago de Chili A moderate earthquake was also recorded at Kew Observatory at 6 h 38 m 31 s G M T on Mar 19 The epicentre is estimated to have been 6080 miles away, but the initial impulse was too small to give any indication of the direction

BY the will of Mr Montague Napier, one of the pioneers of the motor car and aeroplane engine industry, cancer research will eventually benefit to a considerable extent After several bequests have been made, the residue of the estate is left, subject to a life interest, "for the advancement of knowledge and the benefit of mankind by research, whether in the United Kingdom or abroad with the object of ascertaining the cause of cancer (including corresponding or allied diseases) and the means of its prevention, cure, and alleviation, in the discretion of his trustees" The amount available for charitable purposes is expected to be about £700 000

A SPECIAL exhibition of apparatus and equipment used in geophysical surveys was opened in the Science Museum, South Kensington, on Mar 21, and will remain on view for a period of three months The exhibits have been specially selected to illustrate the development of all the important methods at present employed in the location of mineral deposits by the use of sensitive physical apparatus, as well as the evolution of the instruments and apparatus used Details of field operations and the technique of the various methods are also represented, while in addition many examples are shown of results obtained by geophysical surveys in various parts of the world Several of these results, which are now made public for the first time, demonstrate, in a striking manner, the possibilities of geophysical methods of exploration, in revealing the characteristic features of subterranean structures and mineral deposits

AT the stated general meeting of the Royal Irish Academy held in Dublin, Dr R Lloyd Praeger was elected president in succession to Prof R A S Macalister The following officers were also elected Treasurer, Mr F E Hackett, secretary and secretary to the Science Committee, Prof J J Nolan, secretary to the Polite Literature and Antiquities Committee, Mr T P Le Fanu, librarian, Dr E J Gwynn, resident secretary, Mr A Farrington New members elected included Mr T S Broderick, lecturer in mathematics and statistics, Trinity College, Dublin, Prof T Dillon, professor of chemistry in University College, Galway, Rev H V Gill, *S J*, author of numerous papers on physics and geophysics, Dr J H J Poole, lecturer in physics in Trinity College, Dublin Elections to honorary membership included Prof Erwin Schrödinger, Berlin, distinguished for his work in theoretical physics, and Prof Ludwig Diels, Berlin, for his eminent work in systematic botany

A USEFUL catalogue of books in a new condition, on all branches of chemistry has just been issued by Messrs H K Lewis and Co, Ltd, 136 Gower Street, W C 1 Being carefully classified, it should be of service for reference purposes

LIBRARIANS and others wishing to add to their store of scientific periodicals or to fill up gaps in those upon their shelves should obtain a copy of *Periodica*, New Series, No 4, just circulated by Messrs W Dawson and Sons, Ltd, Cannon House, Pilgrim Street E C 4, in which upwards of 700 scientific serials are listed

APPLICATIONS are invited for the following appointments, on or before the dates mentioned —A whole time instructor of metalwork at the Shoreditch Technical Institute—The Education Officer (T 1), County Hall, S E 1 (April 1) An agricultural inspector under the Department of Agriculture for Scotland—The Establishment Officer, Department of Agriculture for Scotland, Queen Street, Edinburgh (April 7) A lecturer in geography at the University College of Swansea—The Registrar, University College, Singleton Park, Swansea (April 11) A science master at the Royal Naval College, Dartmouth—The Headmaster, Royal Naval College, Dartmouth (April 13) A superintendent of instruc

tion in the principles of boot and shoe manufacture under the Northamptonshire County Council Education Committee—The Secretary for Education, County Education Offices, Northampton (April 13) A Dickinson research travelling scholar in medicine, and a Dickinson research surgery scholar at the Manchester Royal Infirmary—The Secretary to the Trustees, Royal Infirmary, Manchester (April 18) An assistant lecturer in geology at the University College of Swansea—The Registrar, University College, Singleton Park, Swansea (April 18) A lecturer in physiology in the University of Bristol—The Secretary and Acting Registrar, The University, Bristol (April 24) An assistant lecturer in education at the University College of Hull—The Registrar, University College, Hull (May 6) An assistant lecturer in geography at the University College of Hull—The Registrar, University College, Hull (May 9) A professor of chemistry in the University of Sheffield—The Registrar, The University, Sheffield (May 15) A Pilkington fellow in cancer research, an Amy Henriotta Worswick fellow for the investigation of the causes and treatment of rheumatoid arthritis, and a Knight fellow for the study of the factors concerned in the development of the symptoms of mental disturbance, in the University of Manchester—The Registrar, The University, Manchester (June 1) A temporary lecturer in educational psychology and hygiene at Goldsmiths' College—The Warden, Goldsmiths' College, New Cross, S E 14 A research fellow at the Liverpool and District Hospital for Diseases of the Heart—The Secretary, Heart Hospital, Oxford Street, Liverpool A junior chemist at the Rubber Research Institute of Malaya—The Secretary, London Advisory Committee, 2 Idol Lane, Eastcheap, E C 3

Our Astronomical Column

Total Eclipse of the Moon—It is several years since a total eclipse of the moon has been visible under favourable conditions in the British Isles Advantage should therefore be taken of the occasion on April 2, though the moon's altitude will not be great In London, the sun sets at 6 33 P M, the first contact with the umbra having occurred 10 minutes earlier, totality begins at 7 22, and lasts for 1½ hours, the last contact with the umbra is at 9 52

Observations of occultations of faint stars during totality can be utilised for obtaining improved values of the moon's diameter and parallax, also studies of the colours and degrees of brightness of various regions of the moon's disc enable inferences to be drawn as to the transparency of the earth's atmosphere in the regions where the moon is on the horizon Mr L Richardson contributed several papers to the B A A *Journal* on this subject, he showed that it is only the lower layers of the earth's atmosphere that are effective in refracting light to the central regions of the umbra

Who discovered Jupiter's Satellites?—J H Johnson, in the B A A *Journal* for January, vindicates the claim of Simon Mayer to have discovered the four great satellites of Jupiter some days before Galileo, and to have deduced better values of their distances from Jupiter and their periods than those of Galileo He gives long quotations from the original documents, and refers to J Bosscha's paper in *Archives Néerlandaises des Sciences*, 1907 Galileo himself denounced Mayer, but his attacks appear to have been unjust, and a good deal of evidence is given in the paper that Mayer's work was independent His values for the diameter of Jupiter and the radii of the satellite orbits suggest that his telescope gave better definition than Galileo's did He received two excellent lenses made by John Baptist Lenccius, of Venice, early in 1610, but he had observed the satellites with another telescope in December 1609 In explanation of the fact that neither he nor Galileo noticed satellite IV on Jan 8, 1610, it is pointed out that it was then at elongation, far outside the other satellites, and that there were other stars of similar brightness near it Mayer was the first to publish tables of the satellites Bakhuyzen has shown that a fixed star which Mayer inserted in a sketch taken on Dec 30, 1610, is in the right place, this adds weight to the genuineness of Mayer's observations Most modern works continue to give Galileo's name as the sole discoverer, so it is well to direct attention to Mayer's claims

Eros—Signor L Jacchia, of Bologna, discusses the light variation of Eros in *Astr Nach*, 5761 He finds for the period of variation 0 10973 days, most observers consider that the true period is twice as long, being formed of two waves that are similar to each other but not quite identical The magnitude at minimum changed from 12 04 on Oct 27 to 10 96 on Nov 23 The amplitude of the light variation is given as 1 12 magnitude on Oct 22, 1 08 magnitude on Nov 12, 1 26 on Nov 23

Report of the Naval Observatory, Washington, for 1930—Details are given concerning the sending and reception of wireless time signals The maximum error of the Annapolis signal was 0 21 sec, the average error 0 038 sec The signals from Rugby and Bordeaux were received on most days

The Nautical Almanac for 1933 is practically completed The list of stars with ephemerides has been increased by 36 A new star catalogue is being formed from 72,330 observations made with the 9-inch transit circle between 1913 and 1926 A table comparing the mean declinations of fundamental stars in different zones with those in various standard catalogues is given in the report The 26 inch equatorial was used for observing the satellites of Jupiter and Saturn, also comets, minor planets, and occultations of stars by the moon Photography of the sun was continued, photographs were secured on 308 days, which is a record number The connexion of sunspots with magnetic disturbances and radio transmission is being investigated Predictions of magnetic storms have been occasionally issued by post card An expedition was sent from the observatory to Honey Lake, Calif, for the eclipse of April 28, 1930 The corona could not be photographed, but the position of the central line was fixed, and found to be very close to the predicted one A collection of 625 books belonging to Prof Asaph Hall, jun, was presented by his widow to the observatory

Visitors are admitted to the observatory on Thursday evenings, 2824 visitors came during 1930 and they were shown objects of interest with the 12 inch equatorial

Research Items

Population and Immigration.—In 1751, Benjamin Franklin wrote his "Observations Concerning the Increase of Mankind and the Peopling of Countries" and concluded that the importation of foreigners into a country does not necessarily increase the population, but that if the immigrants are more industrious and frugal "they will gradually eat the natives out". This thesis is supported by W. A. Rollins (*Jour. of Heredity*, vol. 21, No. 9), who analyses the census changes in the United States since 1650 and their relation to immigration. He shows how the originally high fertility of the early colonial stock declined very slowly until about 1850, when there was a great increase of immigrants, after which the decline was rapid. He also shows that for different parts of the country a high rate of immigration coincided with a low birth rate and vice versa, and that while the immigrants have been chiefly labourers, the fall in the birth rate has been most marked among university graduates, the ultimate effect being the replacement of the educated stocks by immigrants and their descendants. The character of the population of New England has been deteriorating in this way at least since 1850 and probably earlier, and the author suggests that the cycles of civilisation are sometimes correlated with a differential birth rate, the ascent taking place during a period when superior stocks have more children than inferior ones.

Mound Burial, Beech Bottom, Ohio.—The excavation of a small mound on the Ohio River in July–August 1930 is recorded by Charles Bache and Linton Satterthwaite, jun., in the *Museum Journal* (Philadelphia), vol. 21, Nos. 3-4 (Sept.–Dec. 1930). The mound was found to contain a grave in which was a skeleton richly decorated with shell and copper beads. Objects in considerable numbers were found in the sand thrown from the grave and the dark earth which had been used to fill it. Stone objects for the most part were of flint or flinty material, in number 116, of which 70 were thin blades, stemmed or leaf shaped, averaging about 10 cm. in length. The remainder were small points and scrapers. More remarkable was the persistent occurrence of tubes, all, with one exception, of grey pipestone. Thirty-two were found. Of these, seven were complete, two being entirely unbroken. The lengths ranged from 10.8 cm. to 31 cm., the maximum diameter being 2.3–3.8 cm. Ten celts were found, some of hæmatite. Tubes similar to those found here have been found but rarely, especially of such size and in such number. Various uses have been suggested, such as shaman's blowing or sucking tubes, whistles, and so forth, but there has been some disinclination to regard them as smoking pipes. In two, a clay and a charcoal pellet were discovered. In similar cases elsewhere it has been suggested that these were intended to keep the liquid generated in smoking from the mouth. The breaking of the tubes had taken place prior to excavation, and, it is believed, was intentional for ritual purposes. It is suggested that the mound belongs to the Adena culture of the Ohio area. This culture is little known and is only now beginning to be defined. Its chief characteristics are small conical mounds, singly or in groups, uncremated burials in log cists, the use of copper, mainly as ornament, the use of mica, sculpture in the round, and the use of tubular tobacco pipes. The culture is linked with the little-known culture of the Kanawha Valley, West Virginia.

Pearl Fisheries of Sulu.—Florencio Talavera in a paper published in the *Philippine Journal of Science* (vol. 43, No. 4, 1930) has brought together much information on the present situation of the pearl fishery in the Sulu Archipelago. This is a large natural pearling ground, the largest and most prolific in the Philippines, bounded by the Sulu Sea on the north and the Celebes Sea on the south and east, extending for 137 miles in a south-westerly direction from Basilan to Borneo, and consisting of two main groups of islands divided into many smaller islands, islets, and reefs. In the deep water, there are 'pockets' or pearl beds that serve as natural nurseries from which millions of eggs are produced and scattered by the currents, and these settle on the shallow banks. This constant supply is apparently the explanation of the fact that the pearl beds have not been depleted after many years of fishing. The north-east and south-west monsoons naturally regulate the fishing, bringing about a rotation in the working. The Philippine pearl oyster *Margaritifera maxima* grows rapidly, for there are no cold spells to retard its growth. It is sexually mature in two years and attains 14 cm. "nacre measurement", the "present legal size", in about three or four years. It is recommended that this minimum legal size be altered to an outside measurement, as it is difficult to measure accurately the extent of the nacre, and that the Departmental order which restricts the fishing to certain times be rescinded. The present fleet is apparently too small to do any serious damage to the fisheries, and the pearling boats do not as a rule work on the known grounds only but do a considerable amount of prospecting, new beds being discovered continually. It is also recommended "that no protective measures for all beds or any banks within the Sulu Archipelago be adopted until after a careful study of the fisheries shall have been made".

A Study of Mangrove Crabs.—Dr. J. Verwey has done a most valuable piece of work which is described fully in his paper "Einiges über die Biologie Ostindischer Mangrove-Krabben" (*Treubia*, vol. 12, 2, 1930). The fauna of a mangrove swamp is peculiarly specialised and the crabs live in and out of the slimy mud, each species in its own zone and each individual in its own territory. Notes on the mollusca of the different zones are also given, but the main part of the work is on crabs, especially *Uca signatus*. The genera *Sesarma*, *Metaplax*, *Ilioplax*, and *Scylla* are all represented. The account of their habits and their adaptation to the environment is specially interesting. Five zones are recognised, each zone inhabited by different crabs and molluscs which have certain characteristics in common. They are able to withstand much change of salinity; most of them eat the slime and extract nutriment from it, chiefly minute plants and animals; many of them are amphibious, breathing either by gills or by lungs; all of them dig burrows, of various depths, which reach the underlying water. The peculiar habit in fiddler crabs of waving the large claw is believed by the author to be a demonstration of territorial rights, and not, as is sometimes thought, a calling to the female. It apparently goes on almost continuously. The habit appears to belong only to those species which live very close together, with their burrows adjacent, each feeding on the slimy mud around its own special home. The paper is illustrated by clear diagrams of the burrows, text-figures of the crabs and their appendages, and beautiful photographs showing the various habitats.

The Reproduction of *Polystomella*.—We have to thank Mr. E. Heron-Allen, for the publication of the original notes of Dr. J. J. Lister on the reproductive

processes in *Polystomella crispa* (*Smithsonian Miscellaneous Collections*, Publication No 3067 Volume 82, No 9, 1930) Dr Lister's work on the reproduction of the megalospheric form of *Polystomella* by means of flagellispores has been familiar to zoologists for more than thirty years, and it was also known that he had completed the study of the microspheric form, but although the gist of this work had been published, the actual paper had never appeared This unpublished paper was found after Dr Lister's death and completed and edited from his note books by his friend Mr Heron Allen In 1894 the paper on the megalospheric form was published in the *Philosophical Transactions* of the Royal Society The later work on the microspheric form was only published as a postscript to the earlier paper, and this postscript, slightly elaborated, appeared in his "Foraminifera" in Lankester's "Treatise on Zoology" in 1903, in his presidential address to Section D (Zoology) at the York meeting of the British Association in 1906, and in his evening discourse at the Royal Institution in 1907 The protoplasm of the microspheric form of *Polystomella* emerges from the shell and breaks up into small spheres, each of which becomes a megalosphere Details of the process will be found in these notes, with very beautiful photomicrographs published now for the first time The whole of the note books, slides, and photographs have been presented by Mrs Lister to the Heron Allen and Earland Library and Collection at the Natural History Museum, London

Stalked Buds in the Coral *Echinopora* —Dr H Boschma and Dr J Verwey, in their paper "The Occurrence of Stalked Buds in the Coral *Echinopora lamellosa*, Esper" (*Treubia*, vol 12, 2, Oct 1930), describe the frequent presence of small stalked corallites on the under side of colonies which are partly exposed to light These have been noticed before by Dr Boschma in specimens from a small island in Sunda Strait, but they are now found to be common in the colonies of *Echinopora* in the reefs of the Thousand Islands (especially those of the Bay of Batavia) These corals occur both in sheltered and exposed situations, their form differing in different habitats The principal factor governing the development of these stalked buds appears to be light, but the corallum must have a certain thickness before the buds are formed The paper is illustrated by interesting photographs

Changes in the Proteins of Ripening Rice Grains —Takadoro and Abe (*Jour Faculty Agric*, *Hokkaido Imp Univ*, **27**, 349) record a large number of changes in the composition of rice grains during the last three weeks of their development If correct, some of these are of a fundamental nature, for a study of the nitrogen distribution in the protein extracted as oryzenin shows striking changes during ripening While histidin nitrogen was found to increase progressively, most of the other nitrogen fractions show a maximum or a minimum about ten days before the grains ripen Amide nitrogen, monoamino nitrogen, and particularly cystine nitrogen fall to a minimum at this time Diamino nitrogen, however, shows a maximum, apparently due chiefly to a maximum of arganine In the same way, there is a minimum of ash and of phosphorus, but, curiously enough, a maximum of sulphur in spite of the low cystine The isoelectric point of oryzenin fluctuates in accordance with these changes from pH 4 75 to pH 5 08, being highest when the diamino nitrogen is at a maximum

The Estuary of the Sussex Ouse —Using both physical evidence on the ground and documentary evidence from old maps and descriptions, F G Morris has traced the changes in the mouth of the Sussex Ouse and the effect of these changes in the destinies of the towns of Seaford and Newhaven The account appears in *Geography* for March, and is a useful record to the history of changes in the English coast line In the thirteenth century and probably earlier, Seaford was a port of considerable importance lying in the estuary of the Ouse about a mile north west of Seaford Head The sea did not then reach the chalk spurs of Blatchington and Hawth Hills, which had the river at their feet, separated from the sea by a broad shingle spit that no doubt had been piled up by westerly winds and diverted the river mouth to the east This shingle spit was breached in the sixteenth century and a new river mouth resulted on the site of Tide Mills, which became Newhaven Thus the old port of Seaford was rendered valueless and in time silted up The present outlet of the Ouse dates from the seventeenth century and would appear to be partly artificial Near the mouth was the port of Meeching, which eventually became Newhaven when the original port of that name was rendered valueless by shingle drift and was abandoned The old course of the Ouse is now represented in part by Mill Creek

Excitation of Zinc and Cadmium Spectra —A very full study of the intensity of lines in the spectra of cadmium and zinc when excited by electrons of a definite speed is described by K Larché in the *Zeitschrift fur Physik* for Feb 6 The excitation functions, which vary for different types of transitions in the way referred to by Mr Massey and Mr Mohr in their recent communication to NATURE (Feb 14, p 234) also agree very well with those previously found for the allied spectra of mercury Perhaps the remaining point of least definiteness now is the existence of more than one maximum in the excitation curves for certain lines There is a doubt as to whether this is essentially an atomic phenomenon, or due to the conditions in the discharge tube The results of different observers are not always consistent, and in one case, that of the negative bands of nitrogen, a triple maximum has been reported Dr Larché believes that there is a relation between the sharpness of the maximum in the excitation curves and the average life time of the atom in the excited state from which the transition starts—a long lived atom appears to have a sharp excitation function, and an atom with a short life an excitation function with a less pronounced maximum—and in one case, that of the $1^1S_0 - 2^1P_1$ resonance line of cadmium (2288 A), points out that the double maximum of the excitation function has its counterpart in the existence of two different values for the life time

Inductance Coefficients in Electrical Engineering —In electrical engineering, very considerable use has been made of inductance coefficients in connexion with distributing mains, since Maxwell and Lord Rayleigh first gave the requisite formulæ Recently, in everyday work, it has been customary to compute the inductance coefficients for parts of a circuit The assumption is frequently made that there is a coefficient of 'mutual' inductance connecting these partial coefficients In the February issue of the *Journal* of the Institution of Electrical Engineers, Dr A Russell points out that this is not the case and gives the requisite formulæ He also lays stress on the limitations of these formulæ in practical work, as most of them depend on the assumption that the current density is uniform over the cross section of the cable With high frequency currents this assumption is not permissible, the current distributing itself

in such a way that no magnetic effect is produced in the metal of the conductor This he calls the 'Heaviside' effect He proves that although sheath losses can be computed in certain cases by means of inductance coefficients, the method fails when the sheath surrounds two or more cores carrying polyphase currents In this case, the instantaneous value of the algebraical sum of the currents flowing through a cross section of the sheath may be zero This shows that some of the currents in the cross section are flowing in one direction and some in the other The current density varies both in magnitude and phase as we go round the cross section Many new formulæ are given and some of the old ones are given in forms more convenient for computation

A Neon-tube High Tension Voltmeter —The difficulties that have been experienced in devising voltmeters which will read pressures of 100 kilovolts and upwards have led designers to invent instruments which depend on the distance between spherical electrodes when sparking occurs to give an indication of the voltage Corrections for temperature and pressure have to be employed, and the voltage found is the crest or maximum voltage The effective voltage required in practice can only be known when the law according to which the voltage varies has been determined In many cases, however, especially with modern generators, the assumption that the voltage follows the harmonic law suffices, and so we can deduce the effective voltage from the crest voltage by dividing it by the square root of two Dr L E Ryall read a useful paper to the Institution of Electrical Engineers on Feb 6, on the use of a neon tube as a high tension crest voltmeter The accuracy of the method depends in a large degree on the constancy of the striking voltage of the neon lamp when arranged as a voltmeter To test the lamp, it is made part of a neon tube oscillator consisting of a variable air condenser (0 001 μF max) in series with a resistance of one megohm and a telephone receiver across a direct current supply of 400 volts The lamp is in parallel with the condenser, and the capacitance of the latter is reduced until oscillations cease It is found that, if the lamp has permanent characteristics, the frequency of the oscillations can be increased above the audio range (about 20 kilocycles per second) and the capacitance can be reduced to less than 50 $\mu\mu F$ before oscillations cease When this occurs, there is a sudden change in the appearance of the glow By subdividing the voltage by a condenser divider, it was found that the tube could be used very satisfactorily as a sub standard voltmeter

Liquid Diffusion —The January number of the *Journal of the American Chemical Society* contains a paper by McBain and Tsun Hsien Liu on the diffusion of electrolytes, non electrolytes, and colloidal electrolytes The authors combine the Nernst formula for the diffusion of an electrolyte with that of Einstein for uncharged spherical particles or molecules very large in comparison with those of water, and conclude that a generalised equation for the diffusion coefficient, D, will be $D = iRT/\Sigma(1/U_m)$, where $1/U$ is the resistance to movement of a particular species, iRT being the osmotic term The apparatus used was a Northrop diffusion cell with a diaphragm of sintered glass, and the experiments were very rapid and reproducible For simple electrolytes, the predominant factor is the van 't Hoff factor i, the data for potassium chloride being reproduced to within 2 per cent by the formula when i varied whilst the denominator remained constant This implies incomplete ionisation As an example of the method of summation of the effects due to different constituents in predicting total diffusion, the data for a typical soap solution were analysed and found to be in agreement with previous information The data for sugar solutions show that the viscosity contributed by the dissolved substance is not that which determines rate of diffusion The diffusion column of one substance may, by bombardment of its molecules, accelerate, retard, or even reverse the diffusion of another substance

Ortho-hydroxy Aldehydes —Malkin and Nierenstein in the January number of the *Journal of the American Chemical Society* describe some experiments on the acetylation of phloroglucin aldehyde which are of importance in connexion with the synthesis of flavylium compounds It was known that the usual coumarin reaction does not proceed when phloroglucin aldehyde is heated with acetic anhydride and anhydrous sodium acetate, the product of condensation consisting mainly of 2, 4, 6 triacetoxybenzylidenediacetate, melting at 155°-156° Pratt and Robinson, and Robertson and Robinson, by the action of phloroglucin aldehyde and acetic anhydride, in the presence of potassium carbonate, obtained a substance, melting at 156° 157°, which they considered to be triacetylphloroglucin aldehyde The analysis did not agree well with the formula of this substance, so that the presence of half a molecule of combined water was assumed Malkin and Nierenstein show that this so called triacetylphloroglucin aldehyde is the penta acetate compound prepared in 1903 by Herzig and Wenzel, and that the true triacetyl compound may be obtained by carrying out the acetylation in ether solution with acetic anhydride and potassium carbonate The material obtained by Robinson and Robertson has been the starting material in the synthesis of a large number of anthocyanidins

Constituents of Starch —The work of Maquenne and Roux supports the conclusion that natural starch is made up of two constituents, namely, insoluble amylopectin, which is responsible for the paste-forming properties, and soluble amylose ('artificial starch'), in the proportions of 80 and 20 per cent respectively Effront has recently attacked certain of their hypotheses (*Ann Soc Zymol pure et appliquée*, **2**, 5 , 1930) showing that amylose has the properties of a polysaccharide of the type $(C_6H_{10}O_5)_{18}\ H_2O$ and that it probably results from the hydrolysis of depolymerised starch, and cannot, therefore, be a mixture of reducing sugars with dextrins Amylopectin is characterised by the presence of phosphorus, probably in an ester combination, though the actual nature of the compound in which it is present may vary and produce corresponding variations in the power of gelatinisation of the starch Analogously, the amount of phosphorus present determines the solubility of the amylopectin The author goes so far as to suggest that differences in the properties of these two constituents of starch are due to differences in their physical as distinct from their chemical states The work of Nowopokrowsky and Tschebotarewa (*Kolloid Zeit*, **52**, 302 , 1930) supports the existence of these two substances, though the properties described are not in complete agreement with those observed by other workers These authors explain gelatinisation by the production of a concentrated solution of amylose inside the starch granules, followed by a contraction of the outer skin of amylopectin These papers illustrate the great difficulty, characteristic of studies on starch, in correlating results of different workers who approach the problem from different points and give the same names to substances which are not necessarily identical

The Relation of the Fauna and Flora of the British Isles to those of North America

AT the Linnean Society on Mar 5, Mr H E Forrest opened a discussion on "The Relation of the Fauna and Flora of the British Isles to those of North America" Mr Forrest first summarised the geological evidence on which his hypothesis is based There were two phases of the Great Ice Age (1) Ice-sheet period, (2) glacier period During the first phase the ice came from north west across the Irish Sea, during the second phase it came from the north-east

(1) The ice-sheet originated in the mountainous northern region of the Atlantean continent, which connected Europe with North America This gradually sank Eventually an arm of the sea intruded between the Faroes and Scotland this broke the continuity of the ice sheet and brought it to a stand still

(2) When the ice sheet became stationary, its south easterly thrust ceased Then the local glaciers had free play The Scottish Highlands and the Lake District produced glaciers on a big scale, and these sent forth streams of boulders which spread out west and south west to Ireland, North Wales, and the plain of Cheshire and northern Shropshire The glaciers lasted after the ice sheet had finally melted and gradually retired as the climate ameliorated

In the course of his investigations into the mammalian fauna of the British Isles, Mr Forrest has found that out of sixty four British species—recent and fossil—thirty-two are absent from Ireland The usual explanation is that these reached Britain after Ireland became an island But in the west of Ireland there are many plants and animals which do not occur in Britain Several—such as *Saxifraga umbrosa*—occur only in Spain and western Ireland

Among all classes of animals and plants, many species are common to eastern North America and western Europe Five sixths of American fungi are also British About a hundred phanerogams, including many fresh water plants, have similar distribution, whilst among invertebrates—especially insects and molluscs—examples are numerous

That there was a land bridge between Europe and America in the north is admitted Evidence was offered that there was also a connexion in temperate latitudes, that in place of the North Atlantic there was an Atlantean continent—the northern half mountainous, the southern a plain with great fresh-water lakes Mr Forrest suggests that this continent was the home of all British American species, and that some of them originated in it *Saxifraga umbrosa* undoubtedly did so, and other species classed as Lusitanian by Dr Scharff He also suggests that the Salmonid fishes, including *Coregonus* and *Salvelinus*, and the crustaceans *Mysis* and *Limnocalanus*, originated in the Atlantean Lakes

Dr C Tate Regan said that the examples given to support the hypothesis of an Atlantean continent are just as well explained by the supposition that the northern continents have occupied nearly the same areas since the Eocene, except for connexions between Asia and America across the Bering Sea, and possibly between Europe and America via Iceland The only European species found in North America are northern types that range through Siberia, such as the pike The Salmonids (char, whitefish) said by Mr Forrest to have come from the Atlantic continent are not true fresh-water fishes Char (*Savelinus*) are marine fishes that run up rivers to breed and form colonies in lakes those of the lakes of Ireland and Britain may have entered them in glacial times when our seas were colder and the limit of char in the sea was farther south

If in late Tertiary times the North Atlantic had been filled with a continent, one would expect nearly the same marine fauna on opposite sides of the Atlantic It is only the northern species (cod, herring, etc), found also in Iceland waters, that are common to America and Europe

Dr A B Rendle did not consider the existence of a North Atlantic continent necessary to explain the relations between the flora of the British Isles and North America Existing land areas north of the Atlantic represented an adequate connexion between Europe and America in view of the more favourable conditions known to have prevailed formerly in Greenland The presumed existence of the Atlantean continent suggested a greater similarity between the floras of eastern North America and south west Europe and the Mediterranean than was borne out by facts The Lusitanian element in the European flora finds a more satisfactory explanation as a European, not as an Atlantean outlier Some of the species common to Europe and North America, such as *Pteris aquilina* and *Potamogeton natans*, adduced as evidence by Mr Forrest, have a very wide distribution and have no bearing on the case The distribution of *Eriocaulon septangulare* is remarkable, but it seems unnecessary to invoke an Atlantean continent to explain it

Prof J W Gregory was reminded by Mr Forrest's North Atlantean ice cap of the once assumed north polar ice cap If the glaciation of the British Isles was by ice from a North Atlantic continent, some of its rocks should be found in the British glacial drifts In the absence of such material, the issue depends on the interesting cases of distribution to which Mr Forrest had directed attention

Mr J Ramsbottom said that Mr Forrest's summary seemed to lay unwarranted stress on the distribution of fungi The statement that five sixths of American fungi were British was based on a list published by Mr Carleton Rea and himself after a short visit to the eastern United States in 1926 The list included only larger fungi If the whole continent were considered and all classes of fungi, the proportion would be entirely different. Parasitic fungi were largely specialised to their host plants and consequently could only be common to the two areas where the hosts were The aquatic Saprolegniaceæ had many species in common but they were of world wide distribution The fact that the larger fungi of South Africa and other temperate regions have a large proportion of species in common suggests that fungi cannot be called in to give any support whatever to hypotheses of lost continents, and this is probably the same with all cryptogams having small spores

Dr O Stapf observed that he could not adduce any evidence in favour of Mr Forrest's views from the distribution of the so called Lusitanian elements. The simultaneous occurrence of so many species in Europe and in North America is probably very largely connected with a more northern land connexion in Tertiary times, such as is very generally admitted. A certain percentage, however, may be due to simultaneous northward radiation to both hemispheres from an old common area in the south, for example, *Ericaulon septangulare* and *Brasenia purpurea*, the latter now extinct in Europe There is evidence of an extension of the Lusitanian element along the

coast line which connected Ireland and Scotland with Norway across what is now the North Sea Along the same line northern elements spread southwards and have left relict stations so far south as Ireland, where they mingle with Lusitanian species in Clare Island, the cliffs of which harbour *Silene acaulis* and *Saxifraga hypnoides* in intimate contact This coast is the most westerly extension of land in this part of the Atlantic which we can safely postulate In dealing with such problems it is necessary to consider species not only in relation to their special distribution but also to those of their nearer and wider allies

Dr B P Uvarov stated that in studying zoo geographical problems it is necessary to apply ecological methods Orthopterous insects are particularly suitable for these studies, because of the very small number of British species Three zoogeographical groups may be distinguished amongst British Orthoptera The largest consists of species distributed across Siberia, northern and middle Europe This group originated in the Angara continent of geologists Amongst members of the Angara fauna there are some which occur in North America but they spread via north east Siberia The second element is the Lusitanian (Atlantic), their present distribution points to their having originated in dry rocky land at the latitude of the Mediterranean Sea and Canary Islands The third group belongs to families and genera now widely spread in the sub tropics and tropics, and they are obviously relics of an age when the British Isles together with the most of the northern hemisphere enjoyed a mild tropical climate

Mr A J Wilmott emphasised the point that, with the possible exception of *Saxifraga Geum*, no species of the Lusitanian element of the British flora occurs in North America These species must be relics in Ireland, since there has been no connexion southwards since the glaciation Moreover, these species are not particularly cold shy they ascend to considerable elevations in Ireland There are many species common to Europe and to North America, though the number is being steadily diminished by critical study There are a number confined to Europe and eastern North America, and Prof Fernald has found several restricted in America to the unglaciated parts of Newfoundland and the mouth of the St Lawrence We know that many species with limited distribution to day formerly had a wider area of dispersal There are species which are now known only in the eastern United States and Japan It may therefore be possible that a species occurring only in Europe and the eastern States was originally connected across Asia and not across an Atlantis, and too definite an inference should not be drawn from present day distribution alone A proper analysis of the whole flora may give indications of the history of its development

Dr G P Bidder pointed out that the distribution of the fresh water sponge *Heteromeyenia ryderi* given as western Ireland and eastern North America is from Hanitoch's list of Irish Fresh water Sponges (1895), whereas the later account of Stephens shows that this is one of the commonest sponges of Ireland but restricted to non calcareous districts and occurring in the island of Mull Miss Stephens gives no opinion on the distribution of *H repens*, which occurs in America over approximately the same area and has otherwise been recorded only from Galicia, though she holds that the distribution of *H ryderi* supports Scharff's hypothesis of a land bridge to America from Ireland

Forestry in Kenya Colony.

IN the previous Annual Report of the Forest Department of Kenya Colony and Protectorate, reference was made to the great drought of 1928 The recently published report for the year ending Dec 31, 1929, states that "the drought continued with ever increasing intensity for the first quarter of the year", but long rains followed and recovery was rapid One of the results of the drought was rather serious forest fires, occurring principally on the Aberdares and on the Mau The other visitation with which the Colony was afflicted was a plague of locusts, which, says this report, "showed signs of having passed its peak and being rapidly on the decrease, and a greater spirit of optimism prevailed generally"

Steady progress is being made with the work of selecting new forests for reservation and with the survey of the reserved areas It is pleasing to note that an earnest endeavour is being made to ascertain the degree of stocking in the various forests under exploitation by sawmills Enumeration of growing stock is proceeding apace and two working plans are in operation It had been proposed to form a special working plans party "but no staff was available during the year"

There are several forestry administrations under the Colonial Office to which similar remarks on the subject of inadequacy of staff are to be found in the annual reports It is to be hoped, now that prospects in those forestry services are really attractive, that young men of the right type will come forward for training For without sufficient and efficiently trained gazetted staffs real progress is impossible Under Financial Results, the Conservator (Mr H. M Gardner) writes "With only the comparatively small local market to depend on, it is not possible for the Department to produce a large net revenue It can be considered distinctly satisfactory if the Department can pay its way while the forests are being explored, developed, and brought into a more productive state As the forests are improved and communications become better, production costs will diminish, and it should be possible to develop much wider markets and to obtain a very handsome profit from the Colony's forests" The Conservator's optimism is probably quite justified, but it should be remembered that this will only be possible provided financial support is available to develop the forest estate

As a case in point, the opinion of the Government of India at the time a forest organisation was being introduced into that country, soon after the inauguration (in 1864) of the Indian Forest Service, may be quoted, for its application to several of the colonial forest services may not be out of place The following extract is from a Circular (Revenue—Forests, No 24, dated 23rd November 1867) issued by the Governor General, Sir John Lawrence, in Council, and forwarded with a covering dispatch to the Secretary of State for India "It appears expedient to the Governor General in Council, to state that there are certain cases in which the administration of forests must, like the Irrigation Department, undertake works of public utility the outlay on which, within one year, may not always be covered by the revenue of the year The rule that the forest expenditure shall always be covered by the revenue can, in its very nature, only apply to ordinary expenditure"

On the plantation work in Kenya being carried out the report is most informative 4000 acres were

undertaken during the year—the largest area so far accomplished in any one year, and this in spite of the fact that a large number of blanks, due to the drought of 1928, had to be filled up in the existing plantations before any new work could be commenced This afforestation work is undertaken in several different ways (1) The greater part of the plantations are made on land that has been clear felled for timber and fuel and then cleaned up and cultivated by forest squatters The work, in spite of difficulties, is cheap and efficient The method is analogous to the *toungya* method employed in Burma and elsewhere in India (2) When squatters are not available and when the Department is afforesting grasslands, the area is either ploughed and cultivated by contract or a small sum is paid for ploughing and the contractor is allowed to have the use of the land for two to three years before planting, or again, bush covered land is being afforested by planting trees in lines cut through the bush, the growth being slower, but the bush acting as a nurse to the young trees and keeping down weed growth Of the 4000 acres planted, 1063 acres were afforested by this method This represents an addition to the Colony's forest capital (3) In certain types of forest, for example, *Brachylæna*, *Ocotea*, and some *Podocarpus* forests, natural regeneration, with assistance, is sufficient to replace the timber cut (4) Special attention is being concentrated upon fuel plantations and various exotics are being experimented with, and private planting is being encouraged Both railway and public take large amounts of fuel, the former utilised from all sources, Government and private lands, 13,867,025 cub feet during the year As private resources are cut out, the demands will fall increasingly heavily on the Government forests Fuel is now being supplied in large quantities from *Eucalyptus* plantations formed on the sites of natural forest cut for railway fuel The demand for fuel for domestic and industrial purposes is increasing rapidly round Nairobi and is becoming more and more difficult to supply In a few years, however, large areas of plantations will be maturing, as well as large plantations of black wattle, which is being planted on private land for the production of tanning bark

Kenya is so much before the public at the present time that the operations of the Forestry Department, so far as they affect the future well being of the Colony, appear to merit some prominence

Marine Research in the Mediterranean

THE fisheries of Egypt, though small in comparison with the vast fisheries of the northern waters of Europe, are varied and interesting They comprise the sea fisheries along the northern coast of Africa in the Mediterranean, and in the Red Sea, the Nile and delta lake fisheries, the latter of which in 1928 supplied about three quarters of the whole weight of fish landed in Egypt, and also the valuable sponge fisheries of the North African coast lying in territorial waters between Alexandria and Sollûm, which furnish sponges unrivalled in the world for their excellence of quality

We have received the report of the fisheries for the year 1928,* and amongst other items of interest are given comparative figures of the yield in kilograms per unit area of fish from the delta lakes These lakes are of exceptional interest, extending over huge areas and never exceeding much more than a metre in depth; they form a link between the Nile and the sea, for into their southern margins empty the drains of fresh water that have been drawn from the Nile to irrigate the land, while all but one are connected with the sea The lakes are thus stocked both by fresh water fish and by fish entering from the sea By far the most important fish, however, are the grey mullet, which grow and flourish extremely well under the conditions existing in the lakes, and which, at certain periods of the year according to the species, leave on their spawning migrations for the sea Figures are given to show that during the last eight years the average yield of fishes from lakes Menzaleh, Brullos, Maryût, and Edkou together amounted to so much as 142 kgm per hectare Parallel figures are given for the North Sea as 17 3 kgm per hectare, and for cultivated carp ponds as 65 5-165 kgm For a natural fishery these delta lakes are therefore extremely rich

In 1924 the Office of Fisheries Research was closed down, it was reopened towards the end of 1927 by the appointment of Mr R S Wimpenny as Director of Fisheries Research In the report under review there is little of scientific work published, but it is evident that movements are on foot to establish a department sufficient to attack a few, at any rate, of the many problems of interest that Egyptian waters afford, not the least of which from a biological point of view would be a thorough survey of the conditions in the delta lakes themselves

The Government has ordered a small motor Danish seiner to explore the possibilities of the fishing grounds on the Egyptian coasts and a plea has been put forward for a marine laboratory and necessary scientific assistants, and also for a steam trawler for oceanographic research It is to be hoped that this will soon materialise The knowledge of the fundamental problems underlying the productivity of the sea is essential to fishery research, and, while to administrative officials the immediate gain may appear to be insignificant, it is certain that in the long run such work will prove its value It is to be hoped therefore, that the Egyptian Government will see its way clear to supply the means for the establishment of an active marine biological laboratory, situated as it would be amid surroundings of absorbing interest, with problems such as the interchange of faunas between the Red Sea and the Mediterranean and the effects of the Nile flood, it is certain that information would be forthcoming that would add much to our knowledge of life in the sea F S R

* Ministry of Finance Coastguards and Fisheries Service Report on the Fisheries of Egypt for the year 1928 By R S Wimpenny (Cairo Government Press, 1930) P T 5

University and Educational Intelligence

CAMBRIDGE —Smith's prizes have been awarded as follows —Mr H S M Coxeter (Trinity) Mr H R Hulme (Gonville and Caius) Rayleigh prizes have been awarded as follows —Mr H Davenport (Trinity), Mr B Kuttner (Christ's), Mr J C P Miller (Trinity)

LONDON —The following doctorates have been awarded *D Sc in Physics* to Mr J P Andrews, East London College, for a thesis entitled "Investigation into the Elastic and Plastic Behaviour of Materials" (*Proc Phys Soc*, 1925, 1931, *Phil Mag*, 1925, 1928–29, 1931) *D Sc in Geology* to Mr E Spencer for a thesis entitled "A Contribution to the Study of Moonstone from Ceylon and other Areas and of the Stability Relations of the Alkali Felspars", and a subsidiary contribution *D Sc in Physics* on Mr H Shaw for a thesis entitled "Interpretation of Gravitational Anomalies", and fourteen subsidiary contributions

Applications for grants in aid of scientific investigations bearing on agriculture to be carried on in connexion with a university, university college, or other approved institution or society in England and Wales during the academic year beginning Oct 1 next are invited by the Ministry of Agriculture and Fisheries Conditions on which the grants will be made are to be found on Form A 53/T G, copies of which are obtainable from the Secretary of the Ministry, 10 Whitehall Place, S W 1 The latest date for the return of completed forms of entry is May 15

Secondary education in England and America is the subject of an article by Dr Grizzell, professor of secondary education in the University of Pennsylvania, appearing in the December number of *School Life* This is the fortieth of a series of articles sponsored by the National Committee on Research in Secondary Education, and records some of the conclusions reached as the result of a carefully planned co operative study undertaken by a joint committee of experts of the two countries in 1928 Dr Grizzell recognises the existence in both of a tendency in the direction of wider educational opportunity for the adolescent, but the resultant general reorganisation has been more rapid in the United States The recent development in England of the higher elementary and central schools is compared with the high school movement which began in the United States almost a century earlier He notes also a tendency in both countries to extend the period of secondary education upward The 'junior college' movement in America is the counterpart of the development in England of two year courses of specialised study after the 'first' school examination, but is, to all intents and purposes, a separate institution and avoids extreme specialisation in the academic field The greater part of the article is devoted to a survey of contrasting practices and divergent tendencies which the author has observed in every important aspect of secondary education in the two countries Some of these differences are summed up in the dictum, "To the English teacher, education is dominantly an art, to the American it is rapidly becoming a science"

The United States Commissioner of Education, discussing, in his report for 1928 29, recent significant events and tendencies in higher education, gives the first place to increased scientific investigation of institutional problems and objectives Such investigations have been reported during the year by scores of universities Scientific and semi scientific methods of investigation have been ousting the older methods of philosophy and mere observance of tradition William James's passion for grappling with 'stubborn facts' seems to pervade the learned world, and this is attributed to necessity rather than choice, for the increasing industrialisation, machine production, changing of social customs, and other characteristics of a fast evolving civilisation make imperative a correspondingly rapid adaptation on the part of educational institutions, and for this they find themselves compelled to depend more and more on research and scientific study Changes in general organisation of collegiate work are illustrated by the rapid growth of 'junior colleges' (including the first two years of the traditional 4 years liberal arts college course) the increase in their number during the year amounted to 25 per cent Registration of full-time students in colleges and universities meanwhile increased by only 2 per cent With some of the pressure of numbers removed and with a continued increase in financial support, stress may now be put, says the Commissioner, on quality of output Institutions are studying, as never before, both the quantitative and qualitative demands by society for their human product

Birthdays and Research Centres.

Mar 29, 1890—Dr H Spencer Jones, F R S, H M Astronomer at the Cape of Good Hope

The erection of a large reflecting telescope in the southern hemisphere is an urgent need It should have an aperture of at least 72 inches, since, for many purposes, great light gathering power is essential, and it should be equipped with a spectroscope adapted for one, two, or three-prism dispersion Such a telescope would be available for determining the radial velocities of faint stars, and for the study of distant nebulæ and other problems which are beyond the reach of existing instrumental equipment The full interpretation of many observations obtained with large instruments in the northern hemisphere is dependent upon similar observations being secured in the southern hemisphere

In recent work, the need has been felt of a publication in which are summarised the analyses of spectra for which the multiplet relationships have been investigated The identified energy levels in the atom and the excitation potentials and multiplet identifications of individual lines should be given Many of the original papers are in publications which are not available for reference anywhere in South Africa.

April 4, 1852—Prof A P Coleman, F R S, emeritus professor of geology in the University of Toronto

Recent work along the St Lawrence and near Moose Factory and Churchill on Hudson Bay proves that the marine beds, long known in those regions, include not only postglacial deposits, as usually stated, but also interglacial beds The interglacial sea reached twice the height of the postglacial one The last glaciation in eastern America was much less massive than an earlier one, suggesting that the greater load of ice implied a correspondingly greater depression of the lowlands How close to isostatic equilibrium do such adjustments come, and how much lag is to be expected when the load of ice is removed? Have similar relations been found between interglacial and postglacial marine levels in northern Europe?

Societies and Academies.

London

Physical Society, Feb 6—E B Moss A ballistic recorder for small electric currents The standard thread recorder is so modified that it records ballistic throws in instead of the usual steady deflection By this means, the current sensitivity may be increased at least twenty five times—F J Scrase The instrumental phase difference of seismograph records an illustration of the properties of damped oscillatory systems A discussion is given of the method of interpretation of the maxima shown on the records of earthquakes during the surface wave phase The usual procedure is to treat the waves (which actually appear as beats) as being truly simple harmonic In general, this procedure does not necessarily lead to the correct interpretation In direct registration, the true earth maximum may have occurred one half-period later than the time obtained by the usual correction With galvanometric registration, the maximum may have occurred either one, two, or three half periods earlier than the time indicated by the usual formula due to Galitzin For direct registration, the phase correction at present in use appears to be as good as one of the alternatives For galvanometric registration, the correction suggested by

Somville, which is one half-period less than Galitzin's, should be adopted —H. E. Beckett The reflecting powers of rough surfaces at solar wave-lengths A hemispherical mirror was used for integrating diffusely reflected energy upon a thermopile receiver The paper deals at length with the errors inherent in the method and with the adjustment of the apparatus The theory of the method is simplified by the introduction of an auxiliary specimen which, in particular, renders the observations independent of the degree of blackness of the thermopile receiver

Institute of Metals (Annual General Meeting), Mar 11 —**W F Collins** The corrosion of early Chinese bronzes The patina and patination deposits formed by corrosion have resulted in the formation of definite minerals The Chinese bronzes contain an unusually high percentage of lead This preliminary research indicates that the bronze metallurgy of the early Chinese is distinct from that of the Sumerians —**C F Elam** An investigation of the microstructures of fifteen silver Greek coins (500–300 B C) and some forgeries All the genuine coins showed evidence of striking between dies, as opposed to the forgeries, which, with one exception, were made by casting only Analyses indicated that the coins were sometimes made from nearly pure silver, and sometimes copper was added The forgeries contained copper, and in two cases, zinc —**H J Gough** and **H L Cox** The mode of deformation of a single crystal of silver A single crystal of silver has been tested under alternating torsional stresses with the especial object of studying the formation of twin bands Throughout the tests, however, no definite twin markings were observed, although the surface of the specimen was covered by a complete system of slip bands in good agreement with the maximum resolved shear stress law The choice of silver as a suitable material for the study of the formation of twin bands under applied stress was made on the grounds that in the aggregate form silver is known to twin very readily —**C H M Jenkins** Some properties of metallic cadmium By maintaining cadmium cold during rolling, the material produced possesses properties markedly different from metal which is allowed to warm during this process In the short time tensile tests, worked material is stronger than cast material, but under prolonged stress the cast alloys are inferior to rolled samples Microscopic examination was also undertaken on the various materials produced The X ray examination of samples of hot and cold worked cadmium does not indicate an allotropic modification at room temperature and ordinary pressures, but there are marked differences in properties, which suggest a preferred orientation —**P J Durrant** The constitution of the cadmium rich alloys of the system cadmium-silver The constitution of the alloys of cadmium and silver from 0 to 40 per cent by weight of silver has been re investigated by the methods of thermal and micro graphic analysis The liquidus consists of four smooth curves which intersect with peritectic horizontals at 343°, 592°, and 640° C In the solid state the system gives rise to the following solid solutions (1) extending from 0 to 6 per cent by weight of silver, (2) extending from 18 to 33 5 per cent by weight of silver, (3) extending from 36 2 to 39 per cent by weight of silver —**D Stockdale** The solid solutions of the copper-silver system The mutual solubilities of copper and silver have been determined, chiefly by the method of examining quenched specimens under the microscope As this method fails at low temperatures, further information about the position of the phase boundaries was sought by measuring the electrical resistance of quenched wires A 'differential' method which shows up small, abrupt changes in the electrical resistance of alloys at the temperatures at which they occur is also described —**T P Hoar** and **R K Rowntree** A note on the silver rich aluminium-silver alloys above 600° C Aluminium of high purity and the combined use of thermal and micrographic analysis make possible certain modifications in the previously existing diagram

PARIS

Academy of Sciences, Feb 9 —**Molliard** The relations existing between the various organic acids elaborated by *Sterigmatocystis nigra* In cultures containing insufficient mineral salts, both gluconic and citric acids are formed as oxidation products of the sugars Both can serve as food material for the mould, but citric acid is not formed from gluconic acid —**Paul Marchal** Micropterism and seasonal dimorphism in *Trichogamma* —**André Blondel** The rationalisation of the electromagnetic equations —**M de Sparre** Concerning Foucault's pendulum Remarks on a communication of Charron —Armand de Gramont was elected a free academician in succession to the late Achille Le Bel —**A Buhl** Conoidal propagations in wave geometry Waves derived from the ellipsoid —**Jean Capoulade** Green's harmonic function of a domain of revolution —**Jean Pierre Robert** Mediation and metaharmonic functions —**Georges Calugaréano** A generalisation of Borel's theorem on meromorph functions —**L Tchakaloff** The interval of variability of ξ in the formula

Diary of Societies.

FRIDAY, MARCH 27

ROYAL SOCIETY FOR THE PROTECTION OF BIRDS (at Middlesex Guildhall, Westminster), at 3 —Annual Meeting

ROYAL SOCIETY OF MEDICINE (Disease in Children Section), at 5

INSTITUTION OF ELECTRICAL ENGINEERS (West Wales (Swansea) Sub Centre) (at Electricity Offices, Swansea) at 6

INSTITUTION OF STRUCTURAL ENGINEERS (at Chamber of Commerce, Birmingham), at 6 30 – Annual General Meeting

INSTITUTE OF FUEL (East Midlands Section) (at Technical College, Derby), at 7 —P H N Ulander The Power Consumption of Boiler house Auxiliaries

MANCHESTER ASSOCIATION OF ENGINEERS (Annual General Meeting) (at Engineers Club, Manchester), at 7 —C Longden Developments in Modern Foundry Practice

MANCHESTER LITERARY AND PHILOSOPHICAL SOCIETY (Chemical Section) at 7

INSTITUTION OF MECHANICAL ENGINEERS (Informal Meeting), at 7 — Exhibition of Industrial Kinematograph Films

JUNIOR INSTITUTION OF ENGINEERS (at County Hotel, Newcastle on Tyne), at 7 15 —L Clegg Synthetic Resin Products

INSTITUTE OF BRITISH FOUNDRYMEN (Birmingham, Coventry and West Midlands Branch) (at Chamber of Commerce Birmingham), at 7 30 — T G Bamford The Melting of Cast Iron

JUNIOR INSTITUTION OF ENGINEERS, at 7 30 —C E Prince Light Sensitive Work in Modern Industry

GEOLOGISTS ASSOCIATION (in Architectural Theatre University College) at 7 30 Prof I S Palmer On the Pleistocene Succession of the Bristol District —E M Venables Notes on the Geology of Felpham, near Bognor Regis

MICROSCOPICAL SOCIETY OF WALES (at Cardiff Technical College), at 7 30 —Dr P Morgan The Microscope in Bacteriological Work

INSTITUTION OF STRUCTURAL ENGINEERS (at Merchant Venturers Technical College, Bristol), at 7 30 —W E Francis Testing of Materials.

JUNIOR INSTITUTION OF ENGINEERS (at Metallurgical Club, Sheffield), at 7 30 —J F Webster Notes on Recent Road Transport Legislation

ROYAL SOCIETY OF MEDICINE (Epidemiology and State Medicine Section), at 8 Dr A F MacCallan Trachoma Its Importance as a World wide Disease

ROYAL INSTITUTION OF GREAT BRITAIN, at 9 —Lord Rutherford Helium and its Properties

SATURDAY, MARCH 28

ROYAL INSTITUTION OF GREAT BRITAIN, at 3 —Lord Rutherford Recent Researches on the Alpha Rays (4).

INSTITUTE OF BRITISH FOUNDRYMEN (East Midlands Branch) (at Loughborough College), at 6 —Dr A. B Everest Recent Developments in Special Cast Iron

INSTITUTE OF BRITISH FOUNDRYMEN (Newcastle-on Tyne and District Branch) (at Neville Hall Newcastle-on Tyne), at 6 15.—The Brackiesberg Process for Production of Grey Cast Iron.

MONDAY, MARCH 30

INSTITUTE OF ACTUARIES, at 5 —J B Maclean Notes on the Practical Application of the Contribution Method of Distributing Surplus — W Pollock Variations under Altered Conditions in the Bonus Provided by a Given Scale of Premiums.

ROYAL INSTITUTION OF GREAT BRITAIN, at 5 —General Meeting

INSTITUTION OF ELECTRICAL ENGINEERS (Informal Meeting), at 7 —H Astbury and others Discussion on The Rupturing Capacity of E H T and L T Switchgear to be installed on Consumers' Premises

INSTITUTION OF LOCOMOTIVE ENGINEERS (at Chamber of Commerce Birmingham) at 7 —H Chambers Improvements in Water Pick up Gear for Locomotives

HUNTERIAN SOCIETY OF LONDON at 7 15 —Dr E P Poulton and Dr O Heath Discussion on The Common Cold

TUESDAY, MARCH 31

INSTITUTION OF PETROLEUM TECHNOLOGISTS (at Royal Society of Arts), at 6 15 —Annual General Meeting and Induction of New President, J Kewley

ROYAL AERONAUTICAL SOCIETY (jointly with Institution of Automobile Engineers) (at Royal Society of Arts), at 6 30 —High Speed Heavy Oil Engines

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Scientific and Technical Group) (Annual General Meeting), at 7 —S. O Rawling: Examination of the Newman Exposure Apparatus —A S Newman A New Design of Microscope

SHEFFIELD METALLURGICAL ASSOCIATION (at Sheffield), at 7 30.—Dr S W Fell Gases in Steel (with special reference to Oxygen).

SOCIETY OF CHEMICAL INDUSTRY (Chemical Engineering Group) (jointly with Diesel Engine Users Association, Institute of Fuel, Institute of Marine Engineers, Institution of Automobile Engineers, Institution of Engineers in Charge, Institution of Mechanical Engineers, Institution of Petroleum Technologists, Junior Institution of Engineers, Royal Aeronautical Society, and Society of Engineers) (at Institution of Mechanical Engineers), at 7 45 —Dr S J Davies and E Giffen Injection, Ignition, and Combustion in High Speed Heavy Oil Engines

WEDNESDAY, APRIL 1

GEOLOGICAL SOCIETY OF LONDON, at 5 30

INSTITUTION OF ELECTRICAL ENGINEERS (Wireless Section) at 6 —R Naismith (a) Short Distance Observations on Long Wave Phenomena, (b) Field Strength Measurements on Daventry 5XX

NORTH EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (Graduate Section) (at Bolbec Hall, Newcastle upon Tyne), at 7 15 — Debate

SOCIETY OF GLASS TECHNOLOGY (London Section) (at National Physical Laboratory, Teddington), at 7 30

SOCIETY OF PUBLIC ANALYSTS AND OTHER ANALYTICAL CHEMISTS (at Chemical Society), at 8 —R. C Frederick Carbon Monoxide Poisoning Its Detection and the Determination of the Percentage Saturation in Blood by means of the Hartridge Reversion Spectroscope.— H M Mason and G Walsh Experiments on the Hardness of Fats.— Dr B S Evans A New Process for the Determination of Small Amounts of Bromide in Chloride.—S G Walton and R G O Brien The Use of Bromine as a Reagent in the Determination of Alkaloids

ROYAL MICROSCOPICAL SOCIETY (Biological Section) (at B M A House, Tavistock Square).

PUBLIC LECTURE.

SATURDAY, MARCH 28.

HORNIMAN MUSEUM (Forest Hill), at 3 30 —Prof J R Ainsworth Davies Fur bearing Animals in Canada.

CONFERENCE.

SATURDAY AND MONDAY, MARCH 28 AND 30

SOCIETY FOR EXPERIMENTAL BIOLOGY (at Edinburgh).

Saturday, March 28 (in Department of Zoology)

10 A M to 1 P M —J Hammond The Life of the Unfertilised Ovum.

A J M Smith The Problem of the Vitelline Membrane (a) Gas Exchange and Osmotic Equilibria of the Infertile Hen s Egg

J Needham M Stephenson, and D M Needham The Problem of the Vitelline Membrane (b) Lactic Acid Production in the Infertile Hen s Egg

J Needham The Problem of the Vitelline Membrane (c) The Osmotic Properties of the Isolated Membrane

H O Bull Conditioned Responses and Salmon Smolts

W H Pearsall and M Pilling The Physiology of Storage in the Apple

E C Barton Wright The First Sugar of Photosynthesis

(In Department of Animal Genetics)

2.15 to 3 45 —F A E Crew and L Mirskaia (a) Genetic and Physiological Studies on the Hairless Mouse (b) Observations on the Aged Male and Female Mouse

B P Wiesner, P G Marshall, J M Robson H Taylor, and R E Illingworth Recent Experiments on the Dynamics of the Sex Cycle.

3 45 to 5 30 —Demonstrations

5 30 to 6 30 —E Boyd Experiments on Skin Transplantation in the Mouse

E M Gilroy The Effect of Arginine and Thyroxine on the Growth Rate of a Transplantable Tumour of the Mouse

Monday, March 30 (in Department of Bacteriology)

10 A M to 12 15 P M —I J Blake Experimental Infection of *Salmo fario* by *Bacillus salmonicida*

A Cunningham and T Gibson Recent Work on the Filterable Gonidial Stages of Bacteria.

T J Mackie M H Finkelstein and H J Gibson The Natural Antibodies of Various Animal Species.

J M Alston Analysis of Antigens on the Basis of Chemistry and Function

M H Christison Microbic Dissociation with Special Reference to the Tubercle Bacillus

12 15 to 1 —Demonstrations

(In Department of Zoology)

2 15 to 3 45 —A Walton Gas Storage of Mammalian Spermatozoa

A L Craig Bennett Observations on the Influence of Temperature on the Breeding of Animals

A Graham Temperature and *p*H Optima of Invertebrate Enzymes.

3 45 to 4 30.—Demonstrations

4 30 to 6 —J W Gregor Experimental Methods in Taxonomy

V E McM Davey Inheritance of Colour in Certain Species of *Brassica*.

W Black Inheritance of Colour in the Potato Tuber

ANNUAL MEETING.

INSTITUTION OF NAVAL ARCHITECTS (at Royal Society of Arts).

Friday, March 27, at 10 30 A M —Dr H H Blache The Present Position of the Diesel Engine for Marine Purposes.

H E Yarrow Water Tube Boilers in Some Recent Merchant Ships with Service Results.

W H Howden Some Modern Examples of Air Heaters

At 3 30 —E F Spanner Beam Frame Connexions.

SATURDAY, APRIL 4, 1931.

Birth Control and Human Biology

FEW subjects are of greater social significance, or have aroused more violent opposition in recent years, than that of birth control Since Dr Marie Stopes started her energetic campaign ten years ago, she has had to contend with much misrepresentation, together with calumny from certain ecclesiastical quarters It is gratifying to know, therefore, that on Mar 17 a large and distinguished company assembled at the Ritz Hotel to congratulate her upon the success of her pioneer work for the benefit of the human race through the positive control of conception A further indication of the growth of public opinion on the subject of birth control is given by the recent announcement from the Ministry of Health that contraceptive advice may be given in clinics controlled by local authorities, when it is desirable in the interests of health

The society founded by Dr Stopes has the title " Constructive Birth Control " and she rightly insists on the word " constructive " By this Dr Stopes means that her aim is not only to prevent children being born to poor and unhealthy parents, but also to bring the joys of parenthood to sterile couples who desire children and have the means to support them This part of the work of " Constructive Birth Control " must, however, always constitute a very small proportion of the whole, by far the greatest task is that of preventing undesirable births

Now, the means of preventing births—leaving out the illegal and dangerous method of abortion—resolve themselves in two categories, namely (1) prevention of the dehiscence of the eggs, and (2) immobilisation or destruction of the spermatozoa Until recent years methods of the latter kind only have been adopted, and to many people these methods seem disgusting and destructive of all the romance of sexual congress We are, however, coming in sight of much simpler and unobjectionable methods, there is hope of being able to prevent by means of the injection of an extract of pituitary gland the dehiscence of the eggs altogether This injection can be made anywhere on the body, and its effect will last for a whole menstrual period

It is obvious that if the efficacy of the new method referred to can be confirmed and its mode of application standardised, sentimental objections to birth control will disappear there will remain only the ' moral ' and ecclesiastical ones, and on the ecclesiastical objections a word or two

may be said in the interests of clear thinking and accurate history Whatever weight there may be in these objections, they derive no support whatever from the recorded sayings of the Founder of Christianity or from those writings of His great apostle Paul which are most widely accepted as genuine For, from the sayings of Jesus and the writings of Paul, it is clear that both held the view that the present order of Nature would be terminated after a brief period of about forty or fifty years and be replaced by a supernatural order miraculously introduced from heaven, which would establish the "kingdom of God", in which there would be "neither marrying nor giving in marriage" In the meantime, marriage was legal as a concession to the flesh but it was futile and "it remaineth that those with wives should be as those that had none" With an outlook on life and the future of the world so totally different from our modern one, the question of the necessity of birth control could never have presented itself to early spiritual teachers

Dr Stopes was led to advocate birth control from observation of the misery, pain, and disease caused by the overbreeding of the poor Many ladies of great refinement and initial prejudice against birth control have been driven to the same conclusion as Dr Stopes, from the same cause In her book, "The First 5000", Dr Stopes has given heartbreaking accounts of women looking like old hags at the age of thirty five, never free from pain, having forgotten what normal good health means, who, when examined in her clinic, have been discovered to be suffering from displaced wombs, lacerated cervices, and other injuries Such women frequently had histories of annual confinements often resulting in still births, and indeed, from the condition of the womb, it was difficult to see how any other result was to be expected

It has been objected that only unhealthy women would visit the clinic, and that the great majority of working class mothers remain healthy and strong in spite of having had large families in fact, it has been contended that in a normal woman, child bearing, instead of injuring, actually promotes health It may be that Dr Stopes has drawn too dark a picture, but it must be remembered that Dr Jansen- a leading Dutch authority on maternity and heredity—in a book entitled "Feebleness of Growth", comes to the conclusion that, in cases where the influences of alcohol and of venereal disease could be excluded, the members of large families showed a progressive deterioration in size and strength as births succeeded one another This deterioration was not due to any inherent differences in the germs, for when, as in some cases, one or two children died in early infancy, the next surviving child was actually stronger than the last one, showing that the real cause of the deterioration was the exhaustion of the mother But, however important these humanitarian considerations may be, and however much all kindly disposed persons must sympathise with Dr Stopes in her fight against misery and pain in her own sex, there are biological arguments in favour of birth control which enormously outweigh the philanthropic ones and in our opinion erect the question of birth control into the most urgent and important problem of modern times

Dr Elton, in his charming text book on "Animal Ecology", puts the problem most clearly by pointing out that if the numbers of a species are to remain constant, the number of offspring which survive their parents must not exceed two But every known species produces far more offspring than this Suppose now the conditions of the environment to become temporarily more favourable and that three children survive each pair of parents This would mean an increase in the population of 50 per cent in one generation If we represent the original population as 100 and the same increase continued for another generation, the population would increase by 50 per cent over 150 that is, it would reach the figure of 225 and be more than doubled in three generations It is easily seen that in these circumstances the numbers of the species would rapidly attain the dimensions of a plague, and, as Dr Elton shows, at this point a mad impulse to migration sweeps over it, and in rapidly breeding animals like rodents these crises tend to occur at intervals of ten to eleven years

Dr Uvarov has proved that the devastating swarms of migratory locusts develop at intervals out of populations of apparently harmless grasshoppers when owing to the climate in some particular year an unusually large number of eggs hatch out The same thing has been observed in fish After the method had been elaborated of determining the age of fish by counting the rings of growth on their scales, the surprising discovery was made that the herring hatched in a particular year had constituted the bulk of the catch for a long period of years When the matter was inquired into, it was found that the number of eggs spawned in that particular year was not greater than normal, but that owing to the coincidence of the spawning and of a particularly abundant crop of diatoms, far more herrings than usual had survived their

babyhood, so that what had increased was not the *birth rate* but the *survival-rate*

Now, all these phenomena, namely, an increase in survival rate, the consequent abnormal increase in population, and mass migration, have occurred time and again in the human race They are consistently ignored because, man being a slower breeder than most animals, they occur at long intervals and several generations may elapse without their making themselves felt During Classical and Middle Ages there were breeding grounds of hardy, virile races from which swarms of young men issued forth to plunder their civilised neighbours Sometimes these swarms developed into mass migrations, bringing women and children with them Such breeding grounds were the lands surrounding the Baltic the peninsula of Arabia, and the steppes of central Asia Quite obviously, all three regions were incapable of supporting an increasing population, and when the alternatives starvation or migration were presented to them, the sturdy inhabitants invariably chose the latter Nothing more terrible than the Tartar invasions of Mesopotamia, Syria, and Egypt has occurred during human history It may be argued that with the perfection of modern weapons and modern transport such dangers have become things of the past That is partly true, civilised countries are no longer likely to be overrun by hordes of hungry barbarians But the cause of these invasions, the tension of an ever-increasing population, continues to operate and will certainly produce disturbances almost equally as formidable as the Tartar invasions

If we take our own country, we find that in 1600 the population of England and Wales was about 5,000,000, in 1700 it was 5½ million, in 1800 it was 9,000,000, and in 1900 it was more than 30,000,000 The enormous increase in the nineteenth century is usually ascribed to the 'industrial revolution' that is, the introduction of machinery driven by steam for manufacture This, it is argued, provided far more openings for employment, and consequently the poor produced more children But Miss Buer ("Health, Wealth, and Population—the Early Days of the Industrial Revolution") shows that this is a mistaken deduction The increase in population began before the 'revolution' the birth-rate did not increase to any marked extent, but the *survival-rate* increased owing to the introduction of vaccination, modern sanitation, and a purer water supply From 1880 onwards, the birth-rate began to fall, owing to the introduction of birth control methods amongst the well-to-do, but until the present day it remains undiminished amongst the lowest and least skilled section of the population By our grandmotherly system of doles, maternity benefit, etc, we are doing our best to encourage it Forty years ago, this section of the population bred as it does now, but the great majority of the children died To-day, however stupid, they survive and constitute an increasing proportion of the future nation

Before the War, the increase in population was to a considerable extent relieved by emigration to the Dominions and the United States To-day that door is closed, the United States will admit annually only a small quota, and the Dominions, for the present at least, none England at the moment resembles a steam boiler with an increasing pressure and no safety valve In Italy, Signor Mussolini is encouraging large families with the view of increasing the importance of the Italian nation By his skilful development of the natural resources of Italy, room is at present being made for the increase But it is obvious that this process will soon reach its limit, and then Italy will become another dangerous centre of tension

The recent census of India revealed that an increase in the population from 320,000,000 to 350,000,000 has taken place in ten years The Indian peasant always lives on the barest minimum of subsistence, which is all that can be wrung from his small plot of land It makes one shudder to think of the intensification of that dull, sordid struggle and the consequent misery involved in the necessity of feeding 30,000,000 extra mouths A distinguished Anglo-Indian friend once told us that in one of the islands of the Ganges delta three-quarters of the population were wiped out by an inundation, ten years later that island was distinguished by its prosperity over all the other parts of the delta No wonder some cynics sigh for the good old days when, at intervals, life was diversified by plagues and invasions which produced temporary excitement and discomfort and relieved the pressure of population This pressure is one of the results of British rule and British humanitarian sentiment

Humanitarian sentiment acting in ignorance of the laws of biology is a most dangerous thing and produces devastating results Compulsory birth control seems to us to be the only remedy capable of averting these results Truly, though hardness of heart be given divine condemnation, Nature is equally severe on stupidity and wilful ignorance

The Rise and Growth of Applied Entomology

Smithsonian Miscellaneous Collections Vol 84 *A History of Applied Entomology* (*somewhat Anecdotal*) By L O Howard (Publication 3065) Pp viii + 564 + 51 plates (Washington, D C Smithsonian Institution, 1930)

THE title of this volume suggests a severely technical contribution It is, in fact, a technical contribution, but one leavened with anecdotal and humorous facts and foibles respecting personalities that figure in its pages It traces the rise and growth of applied entomology very largely through the lives of those whose efforts have built up the subject The document before us is, in consequence, of a very human interest, and in its author we have the doyen of the world's economic entomologists Dr Howard's long career as Chief of the United States Bureau of Entomology renders him exceptionally well qualified for the task of writing this book Probably no one else has established so many personal contacts with entomologists from all over the world His own travels, so often over North America and into Mexico, and in many European countries, have enabled him to learn much about conditions first hand Further, Dr Howard's office in Washington has long been the Mecca of all entomologists who sought to widen their experience by visiting such American organisations as he advised In his retirement he has made good use of his time by placing on permanent record a rich harvest of facts and impressions gleaned from innumerable sources

This volume is largely divided up geographically into separate parts and, as stated in the preface, it is not a history of the strict, modern, documented type In Part I (pp 9 198), Dr Howard traces the various factors and influences that have led to the great development of his subject in North America Much is related concerning the lives of the early American exponents of economic entomology, their individual traits and how each person influenced the trend of events A good deal is told about individuals and circumstances which we do not recollect having seen in print before As isolated reminiscences these records are merely interesting, but when woven into an historical fabric of this kind, they help to recast a proper perspective of times now gone by. Dr Howard extends just praise where it is due, yet the foibles of individuals are not overlooked, and he manages to incorporate much that is entertaining in an anecdotal way Individuals make institutions, and among the latter the leading State, Federal, and non-official organisations are explained and their developments followed

The inauguration of journals and of societies comes in for its share of recognition, and their metamorphoses are followed up to the present day. The teaching of economic entomology, from its early beginnings up to the great modern schools at Cornell and elsewhere, is recounted teachers and their methods are characterised, while, here and there, something pertaining to their audiences finds expression The major campaigns of insect control in the United States are discussed in an interesting and informal manner quarantine and other acts come in for historical record and their consequences clearly indicated Public expenditure, political events, and also the salaries of entomologists, all come under review Canada and Mexico find their due places in this section of the volume An exceptionally full account is given of applied entomology in Mexico, possibly because it is so little known, and here it seems perhaps a little anomalous that the more extensive, and older, developments in Canada are discussed in the same number of pages

Dr Howard concludes that the enormous damage incurred by insects demands many more men to cope with it in America, even more than in any other part of the world "Surely", he says, "we appreciate their need more than any other country And that is the reason why the United States stands at the head in applied entomology."

Part II (pp 201 336) deals with European countries It opens with sections on the early writers and their work, and then passes on to discuss at length the effects of the entry of the *Phylloxera* on to the Continent It would seem, Dr Howard says, that this pest proved a blessing in disguise, for the reason that serious work in applied entomology originated very largely in some countries as the result of the check to viticulture administered by this insect He then proceeds with his main subject, taking it country by country The early struggles that applied entomology underwent in order to obtain recognition in the British Isles are admirably followed When we come to later developments, we find an appreciation of the work of the Imperial Bureau of Entomology, and due compliment is paid to the world-wide value of its publications Reference will also be found to the influence of the Development Commission, the Empire Marketing Board, Carnegie studentships, and other organisations that have tended so much to the furtherance of the subject

In dealing with France, the development of the State organisations is traced, and a special section is devoted to personalia with respect to the savant Paul Marchal and the outstanding work accomplished by him Similarly, when we come to Italy, we find just tribute paid to F Silvestri, who is, perhaps, the most learned and experienced general entomologist to-day The accounts of developments in Russia and Poland are particularly enlightening, and Dr Howard's visits to both these countries have enabled him to garner information from personal experience So each country is taken *seriatim*, and there are not many that our author has not visited at one time or another, often on several occasions He is thus able to impart much that is both interesting and significant respecting its leading applied entomologists in every story Even Cyprus, its problems, and its young Government entomologist find a place in this section of the volume

Parts III to VI (pp 339 462) are concerned respectively with Asia, Africa, Australasia, and Central and South America Here, a good deal that is unfamiliar is placed on record, and many little known persons are brought into the limelight and their services appraised Most of us know little as to what has gone on in Uruguay, Guam, or Haiti, for example, but Dr Howard has dispelled this ignorance with many interesting facts respecting both persons and institutions in such parts of the world

Part VII (pp 465-545) is mainly concerned with the growth and development that medical entomology has undergone during the last fifty years Dr Howard's own early medical training has given him a lien towards this aspect of insect control By means of his writings and his personal influence, he has done inestimable service in making discoveries widely known, and in moulding American public opinion into realising the menace of insect-borne diseases This part of the volume is rich in personalia, and we find therein many reminiscences of such leaders as Ross, Blanchard, Grassi, and others, too many for separate mention Biological control, also, has its place in this part the history of the practical utilisation of parasitic and predatory insects is traced, and what has been achieved by way of biological control in different countries recounted The three concluding sections of Part VII are short but to the point In one, the growth of the appreciation of applied entomology by other scientific workers is discussed and analysed This is followed by a numerical comparison of applied entomological literature that has emanated from different countries, and it appears that, in less than fourteen years, no fewer than 23,430 papers and books on the subject have appeared in the world ! Finally, Dr Howard has some cogent remarks on the future outlook for the control of insect pests

At the end of the volume are 51 half-tone plates which contain about 250 portraits of applied entomologists who have contributed, or are still contributing, to the advance of their subject The originals of many of these are in the unique collection that Dr Howard has gathered together and filed in Washington over a long period Many visitors from afar have faced the camera at his instigation, but few realised that they were destined to feature in the present volume ! Following the plates is an 18 pp index listing more than 5000 names of individuals that are mentioned in the text of this volume all, in some way or other, have exercised influence upon applied entomology

We must conclude this notice by extending our gratitude to Dr Howard for giving us quite a monumental volume It is one wherein his own inimitable personal touch has imparted to it a character not only unique and entertaining, but also of enduring interest as an historical record

Scientific Aspects of Disarmament

Scientific Disarmament a Treatment based on the Facts of Armament By Victor Lefebure Pp 320 (London Mundanus, Ltd , 1931) 5s net

In the numerous discussions on disarmament during the last twelve years, the ethical and moral aspects have been emphasised out of all proportion to the other factors The moral aspect of war has been debated for centuries, but has essentially no relation to the problem of disarmament as it presents itself to-day Even if we take the Quaker point of view, we cannot afford to wait for the spiritual conversion of whole nations, civilised and uncivilised, to the same doctrine of non violence There is nothing in history which justifies our relying upon such a transformation for the solution of an urgent and acutely dangerous problem It is indeed this failure to visualise disarmament as essentially a practical problem for our own generation that has led to so much dissipation of genuine moral support into sterile and unprofitable channels Had the energy diffused among a score of peace societies of one type or other been concentrated in definite support and

constructive criticism of the efforts of the League of Nations in this field, there would undoubtedly have been far greater advances towards disarmament As it is, our failure to grapple with the facts of disarmament still allows politicians, embarrassed by the conditional disarmament of Germany under the Treaty of Versailles but unwilling to make a positive contribution themselves, to find an easy refuge in moral and economic platitudes

Disarmament presents itself at the moment as essentially a political and a technical problem, and on the whole the emphasis is on the technical aspect The extent to which the Pact of Paris has changed the fundamental situation is as yet scarcely perceived, and once the logical sequence of the fact—the renunciation of neutrality—has been publicly recognised by the Great Powers, the political situation should no longer offer any real obstacles to progress Indeed, the acceptance of this principle by the United States of America would probably be decisive

On the technical side, it is significant that the study of disarmament which has already been carried out by the League of Nations has demonstrated that disarmament is a practical proposition, and discussion now centres not on the possibility but on the mechanism of disarmament To this discussion, Major Lefebure's volume makes a contribution of fundamental importance Disarmament is largely a technical matter Its successful treatment depends on the impartial analysis of all the relevant facts The failure or halting progress of most efforts in the field of disarmament has been mainly due to failure to visualise clearly the main *objective, and as a result to treatment of the problem in fractions* "Scientific Disarmament" *gives us essentially a projection of scientific method* into the disarmament problem—the application of those principles of observation, analysis, and deduction upon which are based all the advances of pure and applied science

Starting with the assumption—to day a definite principle of international policy—that we can no longer afford to settle our national disputes by war, Major Lefebure views disarmament as essentially the problem of securing sufficient periods of time free from hostilities for the success of the alternative methods of peaceful settlement Before any practical steps can be taken, a really thorough and informed exploration of technical disarmament must be undertaken, and the main purpose of the book is to urge the necessity of such an investigation Without it the efforts of the Disarmament Conference, to be held in 1932, are likely to be fruitless, and failure of such a world conference would seriously prejudice the cause of disarmament for years

Ten years ago, in "The Riddle of the Rhine", Major Lefebure established the vital relation between chemical warfare and industry, and exposed both the fallacy of a disarmament policy which ignored the new agencies of war, and the futility of the abolition of chemical warfare without the elaboration of definite measures of control Industrial developments during the last decade have reduced some of the disparity between the chemical industries of the Great Powers, but in the discussions on disarmament chemical warfare has received cursory or only sentimental treatment In spite, however, of the intricate relations between the various agencies of chemical warfare and chemical industry, the conceptions of armament potential and of conversion lag operate as effectively as in other fields If our normal productive capacity is sufficiently low, the time characteristics of the production of armaments of every type involve a delay of anything from six to eighteen months, which renders quantity limitation a feasible and valuable disarmament measure Great stocks of war chemicals used in industry have no meaning for war unless the appropriate containers or chemical weapons have been designed

The soundness of this argument will be appreciated by all who have been concerned with industrial development or expansion, but the question of type is equally important The facts advanced by Major Lefebure indicate that agreement on the types of armament to be retained and limited, and the sup*pression of all other existing types, is also an essential* condition of efficient disarmament The existence *of private manufacture and traffic in arms appears* to be inconsistent in a genuine scheme for disarmament Even an investigation such as that contemplated by Major Lefebure, however, will require much publicity and very emphatic support from public opinion before its recommendations on these questions of armament types, the traffic and manufacture of arms and of combatant conversion involved in the conscription issue, are accepted in the face of opposition which can well be imagined

A significant fact in the history of armaments is the failure of military authorities to recognise the importance of new types of armament The extent to which chemical warfare dominates the armament field is even yet not generally realised, and it is doubtful whether even military or naval opinion appreciates the degree to which the new agencies

of war have increased not only its deadliness but also the difficulty of forecasting its issue Security is now conditional upon disarmament In such circumstances, uninformed action may create an invisible disparity of armament which may lead to war through encouraging some nation to believe in the possibility of its overwhelming success The only disarmament policy which can hold out any hope of success is one based not on opinions but on scientific investigation of the facts which can be ascertained, and on scientific control of the critical technical factors involved Until such a scientific policy has been elaborated, the political factors are largely irrelevant Once in possession of a scientific policy that is technically sound, the hitherto ineffective moral and ethical forces can be marshalled to overcome any lingering opposition in the political field

We may admit that the application of science has made warfare too dangerous an instrument to be used in national policy, but it is equally true, as Major Lefebure reminds us, that science holds the key to disarmament The problems of control are not insoluble and will yield to treatment along scientific lines The elaboration of a scientific disarmament policy is a task in which scientific workers can help, and is urgent and essential if civilisation is to regain control over the destructive powers released by the application of scientific discoveries A study of disarmament is an integral part of that scientific study of international affairs through which alone can ultimately evolve the logical requirement of the Pact of Paris—a science of peace

---

Positive Rays

Canalstrahlen Von E Goldstein (Herausgegeben von E Gehrcke) (Ostwalds Klassiker der exakten Wissenschaften, Nr 231) Pp iv + 86 (Leipzig Akademische Verlagsgesellschaft m b H, 1930) 4 80 gold marks

THIS selection of the late Prof Goldstein's papers, on positive rays and the cathode glow, is reprinted with only two trivial alterations, both due to Goldstein himself One cannot but admire the accuracy of his observations, especially in the first paper (1886), the ultimate outcome of which is now the mass-spectrograph and the two main methods—Brose's and Stark's—for the electrical resolution of spectra

At the same time, it must be admitted that a great deal which Goldstein described has yet to be fully explained, in particular, the origin of the light which appears on the cathode surface inside the Crookes's dark space, and the exact nature of the curious small bulbs of light which form at a hole in the cathode, or at its side, when the discharge strikes to the back of this electrode Goldstein was careful to point out that the former had probably a dual origin, some of the rays to which it was due coming from the cathode and some going towards it, but the elucidation of conditions at the cathode surface remains one of the major problems in connexion with discharge tubes The position with regard to the bulbs is also obscure, it is known that tubes exhibiting them often, if not invariably, act as generators of high-frequency oscillations, but there is no explanation of why this should be so, or even a satisfactory electrical description of the bulbs, whether they are local concentrations of positive rays or local discharges of an arc type

It is interesting to notice that Goldstein gave the correct explanation of the repulsion of the discharge from the walls in the dark space, and of its attraction in the negative glow (in the dark space, he supposed that the walls acted as an anode, and in the negative glow as a cathode), and also that he came near to discovering Brown and Thomson's shadow method for finding potentials in the dark space The least satisfactory sections of the reprints are those dealing with the ray patterns that form on polygonal cathodes, where he has succumbed to the temptation, always present in discharge work, to spend time on phenomena which are rather beautiful and probably not of much fundamental importance

The publication of these papers in book form is a considerable convenience to anyone interested in research on the glow-discharge, as well as an appropriate supplement to von Traubenberg's appreciation of Goldstein in last year's *Die Naturwissenschaften* K G E

Our Bookshelf.

A History of Modern Culture the Great Renewal, 1543–1687 By Prof Preserved Smith Pp xi + 672 (London George Routledge and Sons, Ltd, 1930) 12s 6d net

SEEKING as we do in these pages for every manifestation of the new spirit in the conception of history, we welcome with especial warmth the first volume of Prof Preserved Smith's "History of Modern Culture" Here is an author who opens his account of the seventeenth century boldly by saying that "of all the forces moulding modern life, science has been the greatest It can be shown that all other changes in society are largely dependent upon this" We have just said 'seventeenth century',

but the author himself is careful to extend his limits on the earlier side to 1543, and calls his period 'The Great Renewal', which he thinks we should interpose between Renaissance and Reformation which precede it, and the enlightenment which follows in the eighteenth century Whatever we may think of this division, it has the great advantage of including at one end the work of Copernicus and Vesalius and at the other the foundation of the Newtonian system, with Galileo and his fight with the Inquisition in the central point

The sciences thus form the subject of Part 1 of the book, the humanities of Part 2, social control, which includes education, religion, and law, Part 3, while literature, art, and morals find their way together into Part 4, called the "Spirit of the Times" This arrangement might, no doubt be improved, and it is disconcerting to find a full and admirable chapter on the arts, to say nothing of literature, inserted as an item in the "Characteristics of the Times"

On the matter, the only comment we feel inclined to make is that Prof Smith looks at the culture or civilisation of his period rather too exclusively through the eyes of the writers of books and the painters of pictures One would like to hear more of what the common people did and thought, and how they lived and moved in the period On this side, G N Clark's recent work on the seventeenth century is an interesting contrast But as a history of thought, Prof Smith's book is easily the best we have seen F S M

Wit and Wisdom in Morocco a Study of Native Proverbs By Dr Edward Westermarck, with the assistance of Shereef Abd es-Salâm el Baqqālī Pp xi + 448 (London George Routledge and Sons, Ltd, 1930) 25s net

In this volume, Prof Westermarck completes his trilogy on Moroccan customs and ideas The three books, "Marriage Customs in Morocco" (1914), "Ritual and Belief in Morocco" (1926), and "Wit and Wisdom in Morocco", are the fruit of nine years' experience of the country and its people, spread over a period of three decades In the two earlier works, Prof Westermarck showed to what advantage he had turned his opportunities for observation from the last we are in even a better position to judge what a wealth of intimate knowledge of the psychology of the people and of their everyday life lay behind his interpretation of custom and belief in the earlier studies

The author has here given the literal translation, with explanatory comments, of a large number of proverbs classified under subjects and the text in Arabic script It may be remarked in passing that there are considerable differences between the written and spoken language, which the author sets forth in detail An introductory essay deals elaborately with the form and content of the proverb, and discusses at some length its significance as an index to the character and culture of the people Prof Westermarck points out that the Moroccan proverb shows very marked traces of the influence of Islam, especially in its attitude to women On the other hand, he adds a much needed word of caution as to the employment of the proverb in diagnosing the prominence or absence of any given feature The fast of Ramadan, for example, is not even mentioned in any proverb To conclude that it was therefore of no importance or significance in Morocco would be entirely erroneous, as it is rigorously observed

Collected Geometrical Papers By Prof Syamadas Mukhopadyaya Part 1 Pp viii + 157 (Calcutta Calcutta University Press, 1929) 4 rupees

The papers in this collection number ten on plane curves and seven on non Euclidean, mainly hyperbolic geometry The papers of the first group include six dealing with such topics as the geometrical theory of a plane non cyclic arc, cyclic and sextactic points, and a generalised form of Böhmer's theorem, in which methods of pure geometry are employed, in several cases new methods of considerable interest In this group, there are also four papers on the general theory of osculating conics, in which the methods of differential geometry are applied in rather a novel manner The papers of the second group also offer some new features, and amongst a number of interesting results may be noted an extension of the well known correspondence between a right angled triangle and a three right angled quadrilateral in hyperbolic geometry, so as to include a regular pentagon The book can be recommended to all who are interested in geometry, whether Euclidean or not, and wish to learn something of the progress of geometrical studies in Indian universities

The Papyrus Ebers Translated from the German Version by Cyril P Bryan Pp xl + 167 + 8 plates (London Geoffrey Bles, 1930) 10s 6d net

Lest intending readers may be disappointed, we hasten to inform them at the outset that this book is not a translation in the usual sense of the German version of the famous medical papyrus obtained in Egypt by Ebers in 1870 It is, in fact, a running commentary with a selection only of some of the medical formulæ or prescriptions taken from "the oldest book in the world"—it dates from 1500 B.C.—and classified according to their subject matter diseases of the alimentary system, minor medicine, minor surgery, the urinary system, diseases of women, of the skin, eye, ear, nose, and throat, and so forth In a few cases only does the author quote the magical invocations which played such a prominent part in the healing art of ancient Egypt

Nevertheless, the prescriptions themselves are a remarkable collection, as exemplifying the curious and bizarre forms assumed by the magical idea The chapters containing the actual prescriptions are preceded by others which deal with the age, history, and form of the papyrus, the pharmacopœia, the mineral, plant, and organic materials

used, and the relations of the gods to disease Prof Elliot Smith has contributed an introduction, in which he briefly reviews the progress of the study of the pathology of ancient Egypt, to which he himself has made no small contribution during the last thirty years, and, secondly, points out the value of the Ebers papyrus as a basis for the com parative study of folk medicine, quoting as an example the use of the mouse in folk-healing, which is found in ancient Egypt and survives in England to day

Differential Equations By Dr Forest Ray Moulton Pp xv + 395 (New York The Macmillan Co, 1930) 24*s* net

DR MOULTON'S book is written on a novel plan, in so far as no attempt is made to cover the whole field of differential equations Elementary methods of solution of standard types of equations, singular solutions, solutions by definite integrals, and partial differential equations are omitted altogether, but general classes of ordinary differential equations, the nature of their solutions and integrals, and general methods of determining them are treated fully and with unusual rigour

There are very complete accounts of the method of variation of parameters, the method of successive integration, including its application to the numeri cal solution of equations, and the Cauchy Lipschutz process Linear differential equations, with con stant and periodic coefficients, are considered fully, particular attention being paid to the cases of mul tiple roots of the characteristic and fundamental equations Finally, there is a chapter on differential equations with an infinite number of variables with astronomical applications The general theory is illustrated by applications to specific problems, including elliptic motion, the sine amplitude function, the deviations of falling bodies, and the damped gyroscope

The book is not one for the beginner, but can be highly recommended to the advanced student who seeks information on the general methods of solution of the types of equations treated, as well as to the astronomer and mathematical physicist who need to apply these methods to particular equations met with in their researches

The Annual of the British School at Athens No 29, Session 1927–1928 Pp x + 351 + 25 plates (London Macmillan and Co, Ltd, n d) 63*s* net

THE twenty-ninth Annual of the British School of Archæology in Athens covers the operations of the School for the session 1927–28, when the major excavation at the temple of Artemis Orthia at Sparta was in the nature of a final clear up The director, Mr A M Woodward, therefore devotes himself to a report on the remainder of the inscriptions, mostly of office-holders, and, with M L Robert, discusses at some length four Hellenistic decrees, of which the number found elsewhere at Sparta is exiguous These deal with a proxeny conferred on a Spartan by Arcadian Orchomenos, decrees in favour of Spartan dicasts by Eretria and Demetrius in Thessaly, and an incomplete decree of Tralles Mrs Woodward deals with an interesting group of archaic terra cottas from the Acropolis, presumably votive offerings to Athena Chalkioikos or the warlike Aphrodite, whose temple was behind the Chalkioikos Mr W A Heurtley, assistant director, has continued his work on out-lying early sites, and describes the excavation of two mounds situated in Chalkidike with settlements of the neolithic and bronze ages, which are compared with sites previously excavated by the School at Vardaróftsa

School Botany By Dr Macgregor Skene Pp vii + 243 (Oxford Clarendon Press, London Oxford University Press, 1931) 3*s* 6*d*

MANY teachers of biology are opposed to the introduction of botany and zoology as separate subjects in the school curriculum before the age of specialisation, the higher certificate phase Nevertheless, there are still plenty of syllabuses of botany designed for matriculation examinations, and it is this standard of work which Dr Skene has had in mind in preparing his " School Botany " Whether many of these syllabuses can be said to be ' covered ' by reference to the flowering plant alone is open to doubt But flouting the examination bogy and taking the book on its merits, as matter for profitable study, it attains distinction in its class The treatment is practical from beginning to end, the plants are really live things, whether in the laboratory or in the field, and so clearly is it expressed that a pupil could do much useful work with very little supervision The style flows easily, contact is made with the historical aspect as well as with the other branches of science, and the illustrations are few but good The book can be specially recommended for use with groups of boys or girls of any secondary school age as part of their general education or as the subject of a holiday task

The Dissection of the Frog By Dr R H Whitehouse and Dr A J Grove Pp x + 101 (London University Tutorial Press, Ltd, 1930) 2*s*

THE type system in anatomical teaching is an unconscionable long time dying, and the frog remains an incongruous figure in the centre of the system Every young anatomist learns that the frog is the type of types, and that every other creature is either a ' lower ' type or a ' higher ' type Yet the frog is but an aberrant amphibian, far from the main stream of evolution, and were it not for its convenient size, widespread occurrence, and prolific breeding, it would probably have been overlooked by the selectors of types This is no disparagement of the very compact little book under review, which, in fact, contains a great deal of useful advice about laboratory practice in addition to a clear exposition of the anatomy of the frog The authors hold out high ideals for the teacher, for the student, and for the work of the class If the time factor makes it impossible to carry out their ideals in the letter, the spirit should result in the replacement of much ineffectual copying by honest thinking

Letters to the Editor.

The Theory of Geological Thermal Cycles.

In a review of the second edition of Prof. J. Joly's "Surface History of the Earth" (NATURE, Feb. 14, p. 227) Prof. A. Holmes makes the rather sweeping statement that the proposed mechanism for the alternating accumulation and discharge of heat seems to be physically unacceptable. He appears to justify this view from Dr. Jeffreys' opinion, who originally based his condemnation of the theory on the fact that there is no periodic solution to the equation giving the heat flow in a solid medium. When, however, change of state occurs in the medium, we have to allow both for the motion of the medium itself and also for the latent heat of fusion, and obviously the original differential equation will have very little bearing on the result. Dr. Jeffreys, in his second edition of "The Earth", has simply solved this problem by assuming that if at any depth the radioactive materials were sufficient to raise the medium above the melting point, then the resulting convection currents would exactly carry off the excess heat and a steady state would again be attained. Mathematically, this is equivalent to assuming that the effective conductivity of the medium would adjust itself to give the required heat flow at the required temperature gradient. It is not often that Nature is so accommodating.

It is possible, nevertheless, to discuss the problem mathematically rather more fully, and I have attempted to do so in a paper on "The Thermal Instability of the Earth's Crust" published in the *Scientific Proceedings* of the Royal Dublin Society, vol. 19, No. 32. In this paper it is shown that assuming a basaltic crust with a definite melting point and latent heat, and a melting point pressure curve steeper than the adiabatic for the liquid state, conditions which ordinary basalt apparently fulfils, then periodic partial melting and resolidification of the crust, if it exceeds a certain depth, appear to be physically inevitable, quite apart from any tidal or other effects. This result certainly must be applied with caution if the crustal materials have no definite melting point. Personally, I consider that if these materials are capable of existing over a certain range of temperature and pressure as two phases which differ greatly in viscosity and total energy content, then it is probable we are justified in doing so. If, on the other hand, they pass slowly from the liquid to the solid or highly viscous glassy state so that their viscosity and energy content at a given temperature and pressure are always single valued, then probably Dr. Jeffreys' assumption would be correct. Enough, however, has been said to show that Joly's original theory of thermal cycles cannot be dismissed as in any way physically impossible or improbable. The whole question ultimately hangs on the real properties of the substratum.

Turning to a second point in Prof. Holmes's review, he objects to Joly's theory on the ground that it leads to an alternation from world-wide tension to world compression, which he says he finds geologically unacceptable. To get over this difficulty he has proposed a system of large-scale convection currents in the substratum in which the stresses in the surface crust are due entirely to this current motion. In this, he neglects the fact that if thermal energy is accumulating at any time in the subcrustal materials, they must tend to expand, due either to ordinary thermal expansion or to increase of volume on fusion, and that therefore such epochs must on the whole result in increased tension in the outer crust. The only escape I can see from this impasse is to assume that the progress of energy accumulation and discharge is not simultaneous over the whole earth. It would appear easier to do this on Joly's hypothesis than on Holmes's modification of the theory. Besides, it is not at all certain that there is no evidence for world wide tension and compression. It is usually held that mountain building epochs, that is, states of compressional strain, are more or less world wide and contemporaneous, and if the evidence for world wide tension is not so obvious, this may be due to the fact that it has largely been taken up in the ocean floor, where its effects would not be so open to our inspection, as Joly has already pointed out. It is perhaps also not without significance that the so called common fault in geological science is a tension fault.

To refer to another matter: the connexion which Holmes has emphasised between the state of the outer shell of the earth and terrestrial magnetism appears to be most important. On Larmor's convection current theory of the origin of the earth's magnetic field, we might expect the strength of the field to increase largely in times of revolution when the subcrustal materials are most fluid. Mercanton, of Switzerland, has already attempted to determine the direction of the field at various geological epochs by investigating the direction of magnetisation of lava flows of different ages, and it is just possible that by measuring their intensity of magnetisation some information as to the strength of the earth's field at the time of solidification might be obtained. The problem is not a simple one, since the intensity of magnetisation would depend, not only on the field strength, but also on the chemical composition of the various lavas, and possibly other variables. It indicates, nevertheless, a new avenue of approach to the problem, which might yield some interesting results.

J. H. J. Poole.

Trinity College, Dublin,
Feb. 24.

When I wrote my review of the second edition of Prof. Joly's book several months ago, I had not seen Dr. Poole's paper, but the ideas which he there treats mathematically were by no means new to me, for I had already envisaged them in a qualitative way in my paper "Contributions to the Theory of Magmatic Cycles" (*Geol. Mag.*, 1926, p. 315 *et seq.*). So far from denying that they have important applications, I have since attempted to develop the principles involved, especially in their relation to problems of petrogenesis. In stating that "Joly's mechanism of alternating accumulation and discharge of heat seems to be physically unacceptable", I had particularly in mind the probable distribution of radioactivity through the whole of the earth's substratum, that is, down to a depth of 2900 km.

Joly and Poole appear to assume the existence of a thick layer of material of basaltic composition through which successive waves of fusion develop, pass upward, and die out, this layer being underlain by a lower layer of crystalline rock. The latter conception has hitherto been tacit, but Poole has given it definite expression in the paper to which he refers. On p. 405 he speaks of "a lower infusible layer, such as probably occurs in the earth's crust". In the light of all the relevant evidence, I can see no reason

for making such an assumption Its adoption implies the belief that the material below the 'basaltic' layer is practically free from the radioactive elements The data and principles of geochemistry (involving in particular the known partition of the radioactive elements between basaltic rocks and peridotites, and between stony and iron meteorites) seem to me to make it incredible that the radioactivity of the deep substratum can be ignored Kimberlite, which cannot be a differentiation product from basaltic magma and presumably comes from a deeper level of the substratum, as convincingly argued by Wagner, provides the only direct evidence yet available, and it confirms the deduction that the substratum is far from being devoid of the radioactive elements But this being so, the substratum cannot yet have cooled to a crystalline solid, it must still be an extremely rigid and viscous glass discharging heat with the aid of convective circulation On this view, the earth has not yet reached the stage of its thermal history when the conditions visualised by Joly—or the still later conditions of contraction adopted by Jeffreys—could begin to control geological events

Dr Poole's second point is fully referred to in my recent paper on "Radioactivity and Earth Movements" (*Trans Geol Soc Glasgow*, vol 18 for 1928–1929, pp 559 606, 1931) The view is there developed that tension arises where ascending convection currents approach the under surface of the crystalline crust and turn along in opposed directions, and that compression arises where the lateral currents of adjacent circulation systems approach and turn downwards One effect of this compression is the local transformation of the material of the 'basaltic' layer into eclogite, a metamorphic change involving marked decrease of volume and consequent sinking of the denser material The convection theory requires simultaneous compression and tension in different regions of the globe It certainly does not imply systematic world wide expansion of the substratum or tension of the crust The internal excess of heat is discharged partly by the slow growth of new geosynclinal or ocean floors over the sites of rising currents, partly by the heating up and fusion of sinking eclogite blocks in descending currents, and partly by igneous activity of the familiar kind, the latter representing effects at and near the surface which are thought to be brought about largely by processes such as those discussed by Dr Poole in his papers on "The Thermal Instability of the Earth's Crust"

Novelty throughout Nature

IF I characterise a kind of evolution as advance through new products towards further novelty, there are many who will roundly deny that there is evidence of anything of the sort Hence a live issue.

(1) Let us first in some way define novelty In a preliminary way one may say that what is new could not be predicted before the event of its first occurrence Here the stress is on 'before the event' After the event, the recurrence of like events in like circumstances may be predictable

A distinction is sometimes drawn between 'real' and 'apparent' novelty, and then it is said Given adequately comprehensive knowledge of Nature, all that is apparently new could have been foretold and is therefore not really new. Such a distinction confuses the issue This or that either *is* new and unpredictable before the event of its first occurrence *or*, as predictable on the basis of knowledge up to-date, it is *not* new

We have then to correlate 'up to date' with 'before the event' One has reference to knowledge, the other to the course of Nature as thus far known Here the emphasis falls on 'thus far' The evolution of knowledge may itself be an advance through new products towards further novelty

(2) Let us now ask What is it that is new? If one may liken that which goes on in an atom, a molecule, a crystal, a living organism, a mind, to a 'game' that is played in the field of Nature, one may submit that in each case the relational conditions under which it is played are new, that the rules of the game are new, that the characterising features (qualities and properties) of the players are new

(3) In any practical inquiry on the part of a specialist in some branch of science, he commonly starts with a state of affairs which is (let me say) 'prescribed', in the sense that this is just the kind of game that he finds already in progress with repeated routine of procedure as heretofore But what is thus prescribed may be the 'recurrence' of that which at some earlier stage of evolutionary advance was new, in so far as the relational conditions of its first 'occurrence' were unprecedented

In further detail, the procedure of the man of science may be on this wise In some advancing process, he selects three stages, spaced at discretion, with or without intervening stages, and he commonly narrows them down, here, there, or elsewhere, so as to get them as close set as possible He then concentrates attention on the mid stage He may deal, for example, with vapour and liquid, liquid and solid, with atom and molecule, molecule and crystal, with matter and life, life and mind In each case he seeks to fill in the 'and' which stands for 'pass age to'

Take the first case of vapour, liquid, solid Having at hand many samples of all three, he learns all that he can of the passage of one to the other under differing conditions But this, though it may suggest, does not bring him face to face with the question of novelty from the evolutionary point of view That question may be thus stated If the cosmic order of advance has been from vapour through liquid to solid, could anyone have predicted liquid (not yet in being) from the platform of vapour in some hot star? Or solid from the platform of liquid on a cooling planet? Or are there new rules of each game which could not be predicted before it was in play?

Similar in principle are, among many others, the questions From the atomic platform could the molecule and the crystal be predicted? From the platform of lifeless matter could life and mind be predicted?

In *all* cases the answer may be, Yes Then the whole course of evolution is devoid of a single example of novelty If in *some* cases the answer is No, we must in some way characterise that kind of evolution in which they obtain and formulate generalisations as to how, when, and where some new game supervenes on those already in play

(4) It may here be said that prediction implies a basis of knowledge, and that on the platform of lifeless matter there was as yet no knowledge Can we escape the predicament in which we are thus placed? Some logicians reply that we can

No doubt, we cannot discuss natural advance save in terms of our knowledge thereof But we can ask whether, given all those generalisations which have reference to the atomic game (let us say), one is in a position to deduce therefrom all the generalisations

which have reference to the molecular game And so on with regard to other games

Apart, then, from an evolutionary order of advance, we now ask Are all games *now in play* such as to enable the skilled logician to deduce from any one of them the rules of all others and the characterising features of the players? If so, no one of them affords an example of novelty

Hence it seems that our cardinal issue largely hinges on a logical issue to be decided by those who know not only the rules of this or that Nature game but also the rules of the game of logical deduction If there is divergence of expert opinion, those who are interested amateurs in logic must leave the decision *sub judice* That still leaves it open to them to believe that there is novelty throughout Nature

(5) Meanwhile, men of science pursue their inquiries and formulate generalisations founded on observation and experiment Let each speak as he finds and thus bring fresh data as grist to the logical mill In the field of animal behaviour I find much that I can predict fairly confidently if I know the precedent life history of the individual That which I can thus predict is the recurrence of such and such a manner of behaving in these circumstances or those

None the less, at all levels of behaviour, I find well organised examples of novelty which I did not foresee In each individual, high or low—but more conspicuously in those of higher status—I find subtle nuances of variation from the stereotyped routine of recurrence The more closely I observe the behaviour of this or that animal, however lowly in estate, the more am I impressed with some tincture of that kind of unpredictable variation which affords an example of novelty at its birth Such unforeseen departures from routine seem to exemplify new products, and they may be stepping stones on a line of evolutionary advance towards further novelty

If this be so, it is novelty that *leads* in the forefront of such advance But it leaves in its wake a trail of prescribed routine We thus pass from novelty in precedent behaviour to relative fixity in consequent routine, subject to the proviso that were there no novelty there would be nothing to fix We pass to certain rules (of 'conditioning', 'inheritance', and others) which are distinctive of the life game as such, rules which are learnt only through prolonged observation and experiment Into these I need not enter, since novelty is my theme

(6) My plea is for the recognition of novelty throughout Nature My thesis is that novelty is no less natural than is prescribed routine If we start with established order in routine, the introduction of novelty may be said to call for some 'alien influx into Nature' The question then arises Whence comes this novelty? The reply of those who keep within the limits they assign to scientific inquiry may be It is no part of *our* business to say whence comes Nature or aught within Nature We leave that to others If we find novelty therein, we are content to accept what we find as we progressively build on the foundations laid by observation and experiment

If, however, novelty in some way leads to routine we must budget for some such generalisation as this When in the course of advance there supervene new relational conditions and new products with new characterising features, the recurrence of these conditions always entails the recurrence of those characterising features

Herein there is nothing which contravenes a deep seated belief in the recurrent uniformity of Nature

Change of Susceptibility of Paramagnetic Salts under the Influence of Light

According to Bohr's theory of atomic structure, the colour shown by compounds of elements belonging to the transition groups is ascribed to the presence of incomplete inner shells in them, and to the small difference in the binding energy of an electron attached to the outer valency and the inner incomplete shell respectively Since the transference of an electron from the inner to the outer shell involves a change in its orbital moment, it is therefore to be expected that under the influence of light absorption the magnetic moment of the absorbing ion would also alter One of us tried to observe this effect several years ago without any success, due, as it appears now, to the arrangement used not being sensitive enough

According to Bohr's theory, the magnetic moment of an atom or an ion can only be due to the presence of uncompensated orbital moments of its bound electrons The hypothesis of the existence of spin moments in electrons introduced by Uhlenbeck and Goudsmit has considerably increased our understanding of intra atomic phenomena Attention has recently been directed by Saha (Nature **125**, p 163, Feb 1, 1930) to the part played by the spin moment of electrons in producing absorption in the visible region in certain paramagnetic salts

Saha advances the view that in a salt, like chromic chloride, the absorption in the visible region is entirely due to the outer electrons of the Cr^{+++} ion The most stable states of the Cr^{+++} ion are ^4F and ^4P, and the next higher ones are ^2H, ^2G, and ^2D The transitions from one to the other are brought about by the reversal of the spin axes of one of the d electrons of the Cr^{+++} ion The average difference in energy between the two sets of terms is about 20,000 cm $^{-1}$ (d – 4916 mμ), which is near the absorption region of Cr^{+++} From this, Saha concludes that the absorption of light in the visible region is due to some of the 'd' electrons changing their 'r' vector from $+\frac{1}{2}$ to $-\frac{1}{2}$

About the same time S Kato has, in a series of papers "On the Absorption Spectra of Salt Solutions" (*Sc Rep Inst Phy Chem Res*, Japan, vol 12, p 230, vol 13, pp 7, 49, 1930), shown that in the case of certain paramagnetic ions of vanadium, chromium, molybdenum, etc, in solution, their absorption spectra contain, besides regions of continuous absorption, also certain regions of selective absorption, for example, in the case of the violet solution of chromium chloride in water, she finds two selective absorption regions with wave lengths 4150 (24,100 cm $^{-1}$) and 5500 (18,200 cm $^{-1}$) These absorption frequencies are, according to her, in fair agreement with those emitted during the following transitions of the Cr^{+++} ion, $^4F' - {}^2H' = 20{,}718$ cm $^{-1}$ and $^4F' - {}^2G' = 14{,}758$ cm $^{-1}$, when the influence of the surrounding water molecules, etc, is taken into consideration The difference between the two observed absorption frequencies is 5900 cm $^{-1}$ and is in good agreement with the mean difference $^2G - {}^2H' = 5960$ cm $^{-1}$

As the transition of an ion like Cr^{+++} from its most stable state to the next higher one represents a reduction of its spin moment, then on the view that the magnetic moment of these ions depends mainly on their resultant spin moments (Bose, *Zeit f Phys*, **43**, 864, 1927), such transitions will always be accompanied by a reduction of their corresponding magnetic moments and therefore of the susceptibility of the salts containing them For some time past we have been engaged in investigating this subject and have obtained definite evidence of the lowering of the paramagnetic susceptibilities of solutions of compounds of iron, nickel, cobalt, chromium, and copper

For example, we took a solution of chromic chloride (green), which according to S Kato has the following absorption regions 4300 mμ and 6100 mμ Light from a mercury vapour lamp was passed through suitable filters to cut off entirely the infra-red radiation and to transmit either 4358 mμ or 5460 mμ and 5790 mμ only, and allowed to fall on a bulb containing chromic chloride (green) solution In the latter case, preliminary observation showed that the line 5460 is very little absorbed by the green chromic chloride solution In both the experiments, a definite lowering of the susceptibility was observed, as indicated by the deflection, in an inhomogeneous magnetic field with a steep gradient, of the small bulb containing the solution, which was suspended from a torsion arm Solutions of nickel and ferric chlorides, copper sulphate, etc, show selective absorption in the near infra red, and the decrease of their susceptibilities due to such absorption have also been observed These investigations, which have so far yielded only qualitative results, are being continued

Negative Attenuation of Wireless Waves at Broadcast Frequencies

ATTENTION has been directed from time to time to negative attenuation observed on wireless waves propagating over land Ratcliffe and Barnett have noticed increase of field intensity with distance in their observations on Daventry (1600 metres) [1] Recently Barfield and Munro also noticed that the field strength of 2LO at a distance of 10 km was slightly greater than the figures calculated according to the well-known propagation equations [2] These

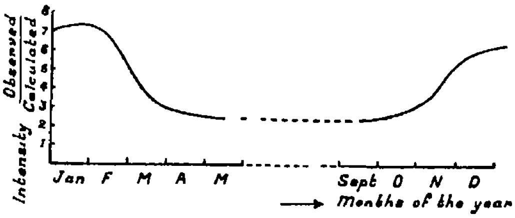

FIG 1—Ratios of observed to calculated values of field intensities of the Bombay Broadcasting Station for weekly averages of observed intensities The broken line represents monsoon period, when observation was impossible, due to thundery weather

observations refer to long waves of the order of 1600 metres or to short distance field strength experiments, at positions so close as 10 km from the transmitter

The present note deals with a type of negative attenuation effect observed on a 357 1 metre wave at a great circle distance of about 640 km Field intensities of the Bombay Broadcasting Station were measured in the laboratories and gave an average ratio of more than 2 5 1 between the observed and calculated values The ratio sometimes reached an abnormal figure of 7 1 in the early part of the year, dwindling down to about 2 1 about the middle of the year (Fig 1) These *consistent* abnormally high signal strengths are believed to be a clear case of negative attenuation at great distance from broadcasting stations

Three features of this service may be mentioned

(a) Excessive fading with periods of very strong signals
(b) General poor audibility with daytime transmission
(c) Abnormally strong signals during wintry months as compared with summer-time reception

It is suggested that the major part of reception is due entirely to the indirect or the sky ray, the ground wave being almost wholly absorbed The topography of the country intervening between the transmitter and the receiver lends support to this view. The former is situated at sea level at the base of a long mountain range, away from the receiver, which is itself about 3000 feet above sea level The mountain range is about 10,000 ft high and covered with dense tropical forest regions This would, no doubt, exercise considerable shielding and absorption effect on the ground ray

The propagation equations having failed to explain these abnormal results, attempts were made to apply Sommerfeld's theory of wave propagation on land, taking account of dielectric constant and ground conductivities The modified equations as obtained by Rolf [3] were used The ground constants and calculated attenuation factors are tabulated below

Authority	λ	Conductivity	Dielectric Constant	Attenuation Factor
Barfield	365	$6\ 4 \times 10^{14}$	10	0 18
Ratcliffe and Barnett	360	$11\ 7 \times 10^{14}$	10	0 025

From these factors, the observed value of intensities would appear to be 14 and 100 times the expected figures Apparently the ground ray is very feeble and the sky ray gives a strong signal of variable intensity It is significant to compare these ratios with the ratio of the observed indirect and direct ray intensities According to Eckersley [4] this ratio is 10 for a wave length of 375 metres and at a distance of 600 km from the transmitter

It is concluded that the negative attenuation effect referred to above is explained by the probability that the observed field strength is due entirely to the indirect ray, all propagation equations applicable to ground level transmissions giving signal intensities which are too low

Variable High Resistance Grid Leaks

THE difficulty of obtaining very high resistances for certain forms of experiment can be overcome by the use of suitable photoelectric cells, as has been suggested by Messrs Adam Hilger, Ltd Not only have these the necessary resistance, but also they can be made to act with controlled variability as variable grid leaks This result we have obtained by mounting the photoelectric cell and grid connexions of a capless valve on amber and vitreosil, the valve itself being suspended in a ring of vitreosil The cathode of the photoelectric cell is attached to the grid, and the anode to whichever side of the filament is found most suitable The cell is completely darkened except at one point where it is exposed to a small lamp lit from batteries controlled by a

continuously variable rheostat The lamp connexions, batteries, and rheostat are contained in a screened tube and box, with the screen earthed to avoid variations due to the adjustment and handling of the rheostat

A large range of high resistance variation can be obtained by choice of the material of the cell and cathode, by the nature of gas used, or by degree of vacuum No battery is required, the difference of potential across the cell being merely the difference of potential between the grid and the filament leg to which attachment is made The apparatus in which use is being made of this variable high resistance is a modification of that described in the *British Journal of Radiology*, March 1930, for detection of the variable electric field of the human body

The Velocity of Light

In Nature of Oct 22 1927 p 602, I summarised the observational evidence respecting the velocity of light In *Astronomische Nachrichten*, No 5530, I pointed out that this evidence is in favour of a decrease of this velocity, which is assumed to be constant owing to considerations of a theoretical order only

I have just heard of a determination of this 'constant' made by Karolus and Mittelstaedt (*Phys Zeits*, vol 29, pp 698 702, 1928) in July 1928 that is, since the last determination (299,796 ± 4 km /sec) made by Michelson at the beginning of 1926 The average of 755 measures gave 299,778 ± 20 km /sec It is remarkable that this is 18 km /sec *less* than the value obtained by Michelson, and falls in good alignment with the last three determinations made in the present century

1902 4	Perrotin	299,901 ± 84 km /sec
1924 6	Michelson	299,802 ± 30 ,,
1926 0	,,	299,796 ± 4 ,,
1928 5	Karolus and Mittelstaedt	299,778 ± 20 ,,

If the velocity of light is constant, how is it that, *invariably*, new determinations give values which are lower than the last one obtained, the observations distributing themselves so as to put in evidence an excellent linear law of variation, as can be ascertained by plotting the above results The graph does not show the slightest sign of a tendency to approach asymptotically a horizontal line It is frankly oblique to the axis of time There are twenty two coincidences in favour of a decrease of the velocity of light, while there is not a single one against it

The velocity of light is affected by magnetism, and the measurements of this 'constant' are performed in a magnetic field of varying intensity, namely, the earth's magnetic field, yet no correction seems to be applied to allow for this variation in the physical conditions in which the experiments are carried out, or in any other which may be present

Vrkljan has shown (*Zeits für Phys*, vol 63, pp 688 691, 1930) that a decrease in the velocity of light is not in contradiction with the general theory of relativity Certainly it is time that the constancy of this velocity should be established beyond doubt on experimental evidence, instead of merely postulated theoretically

The relatively large error of this new determination prevents it from deciding the question A redetermination of the 'constant' by Michelson would settle it once for all

Hydrolysis of Acetone in Ultra-Violet Light

In the course of our investigations on the hydrolysis of acetone in ultra violet light, we have measured the effect of the variation of light intensity on this reaction and found a direct proportionality between incident light intensity and reaction velocity Two sets of experiments were carried out, in one of which the intensity was varied by means of a rotating sector and in the other by using diaphragms of different apertures The results, in both cases, give a fairly constant value of the ratio, change/intensity The detailed results of these experiments and their discussion will be published shortly elsewhere

We have further observed that when aqueous solutions of acetone are exposed in closed plane-walled quartz vessels to the full light of a quartz mercury lamp, as well as acetic acid, formaldehyde is formed in quantities sufficient to be detected and estimated colorimetrically Bowen and Watts [1] could not detect any other product except acetic acid under similar conditions In our opinion, the low quantum efficiency (0 2) found by these investigators for this reaction may be partly due to the formation of formaldehyde Experiments to confirm this idea and re determine the quantum efficiency are proceeding and will be reported in due course

Measurement of the Electrical Conductivity of Electrolytes

In Nature of Mar 21, p 441, M Lecomte du Nouy outlines improvements in the method commonly used to measure the electrical conductivity of electrolytes We are particularly interested in this communication, and think it may be worth while to record that we are making a series of such determinations on solutions of phenol in water, using these modifications, but with the further refinement of a Wagner earthing device We hope to publish results shortly

Red Snow in Persia

On several occasions I have observed 'red snow' on the mountains in Bakhtiari country, south west Persia It usually occurs in patches a couple of yards wide and a score of yards long, lying with normal white snow To day (Feb 14), however, the phenomenon occurred on an entirely different scale a whole mountain side being covered with 'red snow' Two days ago, a heavy fall of snow occurred, lying down to about 6000 ft above the sea level Yesterday was mild and misty, while to day was misty in the morning but clear in the afternoon The mist cleared away from above downwards and had dispersed above 5500 ft above sea level by 10 A M There were a few cloud pennants to be seen infrequently tailing from the higher peaks

Kuh i Javanbin (10,000 ft) and Kuh i Shirgun (9500 ft) are the two mountains on which the 'red snow' was seen Both are smooth topped ridges running north west and south east The south west flank of each is a dip slope of Cretaceous limestone now snow-clad An irregularity at the south east end of Shirgun has produced an extensive facet facing directly

south Viewed at 10 A M, this facet, of the order of 1000 ft high and 2500 ft broad at its base, and situated above the 8000 contour, appeared to be coloured light orange-pink and contrasted strongly with the pure white of the snow on the rest of the south west flank of Shirgun and Javanbin By 3 P M the pink colour had spread all along the south west slope of Shirgun, a matter of 4 miles, and Javanbin was coloured on its lower slopes although the top 1000 ft remained white By this time the original south facing facet of Shirgun was mottled pink and white

The phenomenon of 'red snow' is well known to the tribesmen, who associate the colour with rapid thawing of the snow in the early spring

Forestry Research

THE articles in NATURE of Feb 21 and 28, reviewing the work of the Forestry Commission, prompt me to express the wish that they may be perhaps followed by one dealing with certain aspects of forestry research, more especially with recent work bearing on the importance of biological soil factors in relation to tree growth

For example, the significance of mycorrhiza in nutrition, and the urgent need for laboratory research directed to promote control of its formation in new plantations, have long been matters of concern in the Swedish Forestry Service and are becoming so in those of other countries that is, in certain of the North American States In Sweden, a close working alliance between forestry expert and botanical specialist has already produced significant results

In Great Britain and many parts of the Empire the matter is one of special interest and concern in view of the extensive afforestation of non woodland soils and the use of exotic tree species

M C RAYNER

Bedford College for Women,
Regent's Park, N W 1,
Mar 13

DR RAYNER'S letter is of value since it voices a matter which has already been commented upon in previous issues of NATURE The urgent need of a close co operation between the forester and the specialist, whether botanical, zoological, or chemical, should be beyond dispute The working alliance which has come into being in Sweden—foresters, timber companies, and scientific research centres—will well repay study, as also the amalgamation of various interested bodies in New Zealand The great Forest Research Institute at Dehra Dun furnishes a further illustration Whilst, however, these examples merit the closest study, a slavish imitation of any one by Great Britain may result in wasteful expenditure, and also lead to much overlapping of investigation and research work There are instances where the creation of Government research laboratories paid for out of public funds are justified, if not indispensable for the time being In other cases this is not so Research work can be safely left, and with the certainty of better results, to already existing centres, grants being made by the Government department concerned to cover the cost of certain pieces of investigation work required to be undertaken

It is hoped to consider this question in fuller detail in a subsequent number of NATURE Meanwhile Dr Rayner's recent paper, "Mycorrhiza in Relation to Tree Growth" (published in the *Empire Forestry Journal*, vol 9, No 2, 1930), furnishes an illustration in point.

EDITOR OF *NATURE*

β-Transformation

THE theory of radioactive transformation on the basis of wave-mechanics was initiated by Gamow and Condon and Gurney The consequences have been worked out in detail by Born [1] and Kudar [2] But Heisenberg's objection to the construction of particles out of packets of Schrödinger waves, that they tend to spread out in course of time, has not yet been met

It would be interesting to consider the chances of α and β particles being emitted from the nucleus as such Restricting ourselves here to β radiation and taking into account the relativity variation of mass, it is easily verified that the acceleration (or deceleration) of a fast electron due to the same force is $(1-v^2/c^2)^{3/2}$ of its Newtonian value The electron can, therefore, overcome a higher obstacle under relativity mechanics than under the Newtonian

If E is the total energy of particles inside the nucleus, E' is the minimum energy which enables an electron to jump over the potential barrier, N' is the number of particles inside the nucleus possessing the energy E or more, and N the total number, we see that the radio active properties would depend upon the number N' Using Fermi Dirac statistics, we find

$\dfrac{dN}{dT'}$ always positive and

$$\frac{dN'}{dT'} = \text{const}\left\{\frac{E'T}{e^{\alpha+E'/kT}+1} + \frac{E'}{T'} - \frac{\partial E'}{\partial T} + \frac{3}{2}\int_E^\infty \frac{E^{1/2}dE}{e^{\alpha+E/kT}+1}\right\}$$

Thus N always increases with T' (the temperature inside the nucleus), and, subject to a certain restriction radioactive properties are a direct consequence of increasing atomic numbers More definite conclusions depend on precise knowledge, which is at present lacking, of the potential barrier

The Swimming of Cuttlefish

IN NATURE of June 14, 1930, p 893, F S Russell and G A Steven publish some observations on the movements of *Sepia officinalis*, special attention being given to the part played by the siphon These researches are a confirmation of what was seen by me so long ago as 1912 (*Internationale Monatsschrift für Anatomie und Physiologie*, Bd 39, 1912) and clearly explained in Figs 33 and 34 of my paper (p 129)

OSVALDO POLIMANTI

Istituto di Fisiologia,
R Università di Perugia

WE are indebted to Prof Polimanti for directing our attention to his previously published observations on the swimming of cuttlefish We have not access to the journal in which his work was published, so, unfortunately, have not at the time of writing been able to read it We felt that so obvious a feature in the swimming of the cuttlefish must have been seen before, being unable to find any reference to it, we published an account in the hopes that the information might eventually find its way into English text books, in which the use of the siphon in cuttlefish swimming is given as only for backward darting

Forests, Climate, Erosion, and Inundations

FOR centuries a popular belief has existed that forests induce or attract rain With the progress made in the conservation of the forest on carefully prescribed plans of management, the forester took a hand in the controversy which, with the diminution of the area of forest in the more populous parts of Europe, gradually arose round this matter A considerable literature is devoted to the problem of the influence of forests on rainfall and other forms of atmospheric precipitation Until recently the opinions held and the arguments advanced for and against the effects of the forest on climate have been more or less one-sided and based to a great extent on generalisations

During the last few years this important matter has entered on a new and most promising stage in its history On the subject of the general question of forests and rainfall, etc, two papers representing the opposite opinions held in this matter have been published, the one, "Forests and Water in the Light of Scientific Investigation", by R Zon, of the U S Department of Agriculture (1927), and the other, "The Influence of Forests on Rainfall and Run-off", read by Dr C E P Brooks before the Royal Meteorological Society (1927) Since these two papers, several other important contributions to this subject have appeared In 1929 Mr B O Coventry published a paper on "Denudation of the Punjab Hills" which was reviewed in NATURE of Feb 1, 1930 In the same year a Kenya Forest Department pamphlet appeared entitled "The Influence of Forests on Climate and Water Supply in Kenya", by J W Nicholson (of the Indian Forest Service, now Forest Adviser to the Governments of Kenya and Uganda) and A Walter, Director, British East African Meteorological Service

Previously to Mr Coventry's report, Mr L B Holland, of the Indian Forest Service, had been specially deputed by his Government to make a tour of inspection in the outer hills of the Punjab in 1927 and 1928, his report on the matter ("A Report on Denudation and Erosion in the Low Hills of the Punjab") being published in 1928 At the Punjab Engineering Congress, 1930, held in Lahore, a paper entitled "Erosion in the Punjab Himalaya and its Probable Effect on Water Supplies" was submitted to the Congress by Messrs L B Holland and H M Glover, the latter also of the Indian Forest Service The two latter examples from Kenya and the Punjab are of high interest, since in one case we have at length the necessary association and collaboration of the forestry expert with the meteorologist, whilst in the other an equally important association, where great irrigation works depend entirely upon the permanence of the water supplies, of the forest and irrigation officers

Finally, in *Matériaux pour l'etude des calamités* (No 23, No 3, 1930), issued by the Société de Géographie de Genève under the auspices of the Committee of the International Red Cross and the League of Red Cross Societies, a paper appears, "Les Forêts et les inondations", by MM Delville et J Delévoie At first sight it appeared a matter for surprise to find forestry matters being taken up by the Red Cross But the reason soon became obvious It was one of the most serious effects of erosion, inundations and their often appalling catastrophic effects on the populations in the lower hills and plains, which proved the point of interest to the Red Cross Societies

It may be maintained without fear of contradiction, by those possessing any knowledge of this complicated question of forests, climate, erosion, and inundation, all of which are covered in the papers above mentioned, that the latter in their several ways have made a valuable contribution to our knowledge They mark a distinct step forward in the direction of possible practical results in coping with the several evils resulting from man's ignorant action upsetting Nature's balance between the forests, water supplies, and unforested lands In the present article, more than a brief analysis of these papers is impossible their close study will well repay those interested in these questions, as also those responsible, from the positions they hold, for checking further destruction and undertaking remedial measures to minimise the harm already resulting from ignorance or vandalism

The present position of the controversy on forests and rainfall is well summed up in the Kenya pamphlet by Nicholson and Walter R Zon, the American authority, holds to the belief that forests induce rain, and that the most important influence of forests is their capacity for regulating the flow of surface water, and consequently the streams issuing below them Zon has collected and puts forward to support his views a large number of data and observations, the value of which is fully recognised by the Kenya authors, although they believe that, as also in the case of Dr Brooks, data contradictory to the theories of these two are ignored, whilst unsupported generalisations put forward will not bear scientific analysis Brooks holds the point of view opposite to that of Zon, and his treatment of the matter is on the more scientific plane, though generalisations also appear

As most forest officers who have given thought to and had any practical experience of the problems involved are aware, it is due to the fact that so much theory has been indulged in and so much written that would not bear either scientific analysis or (as, if not more, important) such practical field tests as were feasible, that has led to this question being neglected in the past—in fact, it might even be added, to the question being treated with derision by a certain type of forest officer, by the public, and by the civil authorities The last were only too ready to close their eyes to the damage being done, owing to the outcry which they knew would arise from the people engaged in destroying unchecked the forests which had for so long played their protective part in, as we are now learning, a very varying degree and manner

It is unnecessary to consider here the elementary

ideas upon the direct and indirect benefits of forests from a climatic point of view in different regions of the world Any text-book will afford a summary Zon's and Brooks's publications must be consulted for their full views The pamphlet by Nicholson and Walter is important, since it marks one of the first, it is believed, practical contributions to the possible effects of (*a*) destruction of forests, (*b*) afforestation of certain types of area on the climate, and especially rainfall, in Kenya and Uganda Even if put forward tentatively, they are practical suggestions For example, one of the conclusions arrived at is " that under favourable circumstances mountain forests in East Africa can induce occult precipitation (fog or dew) up to at least 25 per cent of the total annual rainfall " Perhaps the most interesting conclusion of these authors is, however, on the subject of ' instability rain ', to which they correctly assign the importance of a chapter to itself Instability rain is a matter of supreme importance in some parts of the tropics Dr Brooks describes it as due " to the warming up of the surface layer of air to a point at which it is potentially higher than the air above it The potentially light air begins to rise, at first in thin threads which produce scattered cumulus clouds, and finally, if the process continues far enough, in thicker columns which cause cumulo-nimbus clouds with rain and perhaps thunder and hail The potential density of the air depends mainly on its temperature and partly also on its humidity " Nicholson adds a few further remarks to supplement this description " In East Africa instability rain falls on still afternoons usually after bright sunny mornings It is frequently accompanied by thunder and is always very local in its distribution In some parts of Uganda to lessen the contingency of crops failing the natives cultivate two shambas some miles apart from one another Unfortunately the European cannot copy this practice, but where the instability rain is the prevailing form of rainfall he can select a long-shaped in preference to a square shaped farm "

Brooks minimises the possible effects of forests on instability rain It may be accorded, however, to the Kenya authors, as a result of their investigations, that they have advanced good evidence for their present conclusion that " wherever meteorological conditions in East Africa are favourable to the production of instability rain the possibility and quantity of such rain is greatly increased by the presence of forests "

Wind, and its connexion with a general consideration of this question, is dealt with in the Kenya pamphlet, but limits of space preclude further discussion of the interesting data

Allusion has already been made to Mr Coventry's paper on the denudation of the Punjab Hills The report, written as the outcome of an examination made of the lower hills by Mr L B Holland, furnishes evidence that the Punjab Government has at length become alive to the seriousness of the position which disafforestation, excess grazing, and so forth, has brought about over large areas of the lower hills The best known example of the results following the unchecked removal of forest growth on a friable geological formation is the case of the Hoshiapur *chos*, which was being quoted so far back as 1877 Under a mistaken policy, the scrub forest on the hills was apportioned out amongst the villagers With increasing population, increasing demands for fuel, and large calls upon the grazing (owing to the far larger herds now kept, due to the more settled conditions under British Government), the hills were entirely denuded , enormous areas of valuable agricultural land were submerged by the tons of debris brought down through the rapid erosion of the now bare hills, and desolation supervened over part of the area known as the Garden of the Punjab This is well-authenticated history But much devastation of forest, with increasing erosion and denudation, has taken place since, and the position reached is now considered so serious that interference with the water supplies upon which the great Punjab irrigation schemes depend may be a not improbable future contingency The paper by Holland and Glover read at the Punjab Engineering Congress (1930) is an effort to focus the attention of the engineer upon this matter, owing to the serious effect of further unchecked forest clearing in the hills on the water supplies Afforestation is suggested, and the claims of building dams to arrest and catch the water pouring down bare hillsides during rain storms, as against the more natural and stable method of undertaking the same operation by means of afforestation, were discussed

The last paper to which reference has been made is " Les Forêts et les inondations ", by MM Delville et Delévoie This paper is written in the interests of Belgium by the Director General and an inspector of the Forest Service Their analyses of the effects of forests on water flow follow R Zon to a great extent, with whose deductions they fully agree, although they recognise that contradictory opinions are held They refer to the practical experiments on the subject of run-off from forested and bare areas which are being made in Switzerland and in the United States Few dispute the argument that inundations have increased in late years in America, India, Africa, and even in Europe In some cases this increase (18 per cent in the last twelve years in the United States) is directly attributable to disforestation The control work which has been undertaken in Alpine countries in Europe is well known The Japanese are engaged upon large afforestation schemes in Korea, mainly for climatic reasons As a result of their survey of the position, undertaken owing to the serious inundations in Belgium of recent years, the writers of the paper under consideration lay down the following policy for the future " On peut conclure avec la Commission du Conseil supérieur des Forêts, chargée d'une étude sur les inondations, qu'il y a lieu de lutter contre celles-ci

" 1 Par une série de mesures destinées à conserver et à renforcer l'état boisé sur les collines et sur tous les plateaux élevés, dont beaucoup sont encore dénudés

" 2 Par des travaux spéciaux de nature à ralentir la vitesse de l'eau sur tous les ruisseaux à pentes rapide, à allure torrentielle "

The Nature and Scope of Physical Science

II

By Prof HERBERT DINGLE

THE present position of physical science is that a large body of observations have been correlated by the two processes of abstraction and hypothesis Abstraction has led us virtually to a contorted space time, and hypothesis to a scheme of concepts unpicturable by the imagination Both space time and the scheme of concepts, however, by obeying prescribed rules, reproduce the data of observation so that out of pure conceptions, having only a rational meaning, we can evolve, as it were, a very large part of the world of experience This is the great achievement of modern physical science The question that next arises is What is the relation, in the category of reality, however we may define that word, of the world of experience to the connecting world of thought?

The question has been framed and answered by Sir Arthur Eddington and his answer is definite—the conceptual world is symbolic of the world of experience ("The Nature of the Physical World", p xv) But clearly that is not sufficient, otherwise science would be merely a form of art, and there would be no justification for laboriously expressing the obvious in terms of the incomprehensible when any poetaster could give an intelligible symbol of the world with infinitely greater facility Apart from practical considerations, there are, so far as I can see, only two possibilities which can justify such a procedure first, that the conceptual scheme is in some sense truer' than the world of experience, second, that it reveals the existence of a connecting link between the diverse elements of experience The fundamental characteristic of the views of science recently presented by Sir Arthur Eddington and Sir James Jeans is that the former alternative is adopted I venture to suggest that this is a mistake the conceptual world of physics is merely a means of making Nature intelligible to our minds and its laws are not to be interpreted as the truth about Nature

It is impossible here to do more than indicate one argument supporting this statement Since physical conceptions are always changing, any truth they represent must be exceedingly protean in form, on the other hand, the process of correlation of observations goes on continuously, and is, in fact, what directs the changes of conceptions We cannot, therefore, regard the scheme of theoretical physics as telling us anything definitive about Nature, except that Nature appears to be intelligible

An important example of the point at issue is found in the question of determinacy It has recently been found advisable to suppose that there is a kind of indeterminacy in the behaviour of atoms, and this has been interpreted as a recognition of indeterminacy in Nature Such an interpretation seems to subject us again to the error from which we have recently become emancipated We have learned that abstractions (time, space, etc) from phenomena are not to be foisted on atoms, and we immediately celebrate the discovery by foisting the characteristics of atoms on phenomena

There is another example, however, which merits more detailed consideration, namely, the relation of science to measurement Eddington (loc cit, p 275) and Jeans ("The Mysterious Universe", pp 140 141) identify the domain of science with the domain of the measurable, and their great authority has been widely invoked by non scientific thinkers intent on 'putting science in its place' It is usually a very simple matter to decide whether an experience is metrical or non-metrical in character, and a ready solution of many of the difficult questions raised by science is available if we can simply ignore everything that science has attempted to say of non-metrical experiences Artists, theologians, metaphysicians, and moralists are thus enticed into what I believe to be a fool's paradise Not only so, but this false escape from the challenge of science is necessarily accompanied by a real deprivation of its benefits Art and religion have much to gain by a proper use of scientific principles, and the sharp restriction of the domain of science to the metrical elements of experience leaves them the poorer

It is of course obvious that a large part of the data of science is non metrical in character The schoolboy's name for chemistry is 'stinks', not 'balances', and a very appropriate name it is Biologists observe the flight of birds very closely, but they do not trouble to apply the Fitzgerald-Lorentz contraction, not because it is too small to be important but because it has no relation to the *kind* of observation they are interested in It is clear, therefore, that much of the recording and augmentation of our experiences, which is essentially scientific, is not metrical This in itself is sufficient to refute the doctrine in question we need look no further in order to disillusion the non-scientific thinkers referred to above

But this is not the whole of the matter No doubt Jeans and Eddington would admit this readily enough, and still adhere to their opinions For to them observations are just convenient tools for leading us to the truth underlying phenomena it is that truth which they claim is metrical Their doctrine applies not to the collecting of experiences but to their rational correlation, and they would say that when we come to analyse our experiences in order to discover the microscopic scheme of Nature, it is only the metrical elements that we can employ scientifically I observe a cup, for example, and I notice that it is yellow in colour and hard to the touch Those experiences I share with other normal people, and they are not primarily metrical But when they are absorbed into the scientific scheme, it is only the metrical part of them which is used The yellow colour, which I happen to dislike and of which someone else might be very fond, is represented only by a range of

wave-lengths', about which neither of us has any emotions at all The hardness is represented by 'electro-magnetic forces' (or modifications of 'space-time') which are definable by means of equations Through these metrical quantities, all that is scientifically tractable in the yellowness and hardness of the cup is expressed, and the other qualities of yellowness and hardness are left over as belonging, according to Eddington, to the extra-scientific domain of experience, or, according to Jeans, so far as I can gather, to the domain of illusions

This idea, as Eddington clearly points out, requires that science is a closed, self-contained system, including all that is metrical in our experiences But it is difficult to see how the existence of this closed system can be established Even in the metrical part of our experiences there are phenomena which lie outside it Take motion, for example The system includes the motion of a comet, but it does not include the motion of a fly We need consider none of the non-metrical aspects of the fly, but only its motion as a piece of matter The matter is made up of protons and electrons, formed into atoms indistinguishable from those of the comet, and its motion can be described completely in terms of space and time Nevertheless, the motion of the fly is essentially of a different character from that of the comet, it cannot be included within the closed system of metrical physics Although itself metrical, we can make nothing intelligible out of it unless we associate it with something non metrical, which we call 'life', and if anyone thinks that motions associated with life are so entirely incalculable as to be outside science, he should reflect for a moment on the significance of a fly-paper

The fact is that science is fitted to deal with all experiences which are common to all normal people Such of these experiences as are metrical in character are largely—but, as we have just seen, not entirely—susceptible to correlation by the present scheme of physics The others appear to be amenable only to conceptions which are individually different but ultimately of the same character For these experiences also we employ abstractions and hypotheses The abstraction of space time is irrelevant, so we leave it in the phenomena and instead take out such concepts as life, mind, will These are just as truly abstractions as are space and time the 'I' of psychology is as valid a scientific idea as the 'i' of mathematics, and has perhaps still more right to be called an imaginary quantity, for it can at least be imagined Similarly, we employ hypotheses The hypotheses of protons and electrons are irrelevant, so we conjure up such ideas as organic evolution and subconsciousness We observe and we correlate by the same methods as those employed in physics, and to a certain extent we can predict events In every respect our treatment of these experiences has the same character as that of the metrical experiences It appears to be an arbitrary and extremely inconvenient use of language to call the one treatment scientific and the other not

Eddington gives an admirable example (loc cit, pp 251-252) of the supposed limitation of science to measurement He describes an imaginary examination question in which an elephant is assumed to slide down a grassy hillside and it is required to find the time of descent He points out that in solving the problem we do not consider the elephant but merely its mass, namely, 2 tons Similarly, the hillside is represented by a slope of 60° and a coefficient of friction Thus the poetry fades out of the problem and only 'pointer readings' are left

Now the whole secret of the matter is in the object of the inquiry, which is mentioned as a sort of after thought "The question presumably was to find the time of descent of the elephant" Naturally, since the time of descent is essentially a metrical quality, we should expect the relevant parts of the data to be metrical in character But suppose the further question is put "To find the damage done to the elephant" "Two tons" is of no use now, the living, struggling, trumpeting animal must be reckoned with We can do without a knowledge of the slope of the hill, and the coefficient of friction 'leaves us cold' As before, the poetry fades out of the problem, and it takes the metrical elements with it, but there is still something left, and that something is scientific in character It involves such things as abrasions and broken limbs, it is approachable with chloroform and X rays, the problem requires a knowledge of the anatomical structure and physiological processes of elephants—that is, scientific knowledge, and the answer can be stated in scientific terms conveying the same meaning to all normal people

The division of common experience into metrical and non-metrical parts, of which only the former can be dealt with scientifically, therefore appears too simple The whole of common experience is open to scientific treatment, part of that which is metrical is included in the physical scheme, and the remainder, together with the non metrical elements, must be placed in a different scientific category—or perhaps more than one such category Even this does not exhaust the potentialities of science, for it has an influence outside its own proper sphere, namely, among those experiences which are peculiar to the individual Such experiences are not in themselves subject to scientific treatment but, by virtue of a parallelism which exists between them and experiences which are so subject, they cannot be considered as if they were altogether independent of science, or, rather, if we do so consider them, we are closing our minds to much relevant information It is common knowledge that a man's temper, which is outside the scope of science, shows a close relation with the condition of his digestion, which is very largely, at least, susceptible to scientific treatment

This point, though sufficiently obvious, is widely overlooked It is frequently supposed that by defining the field of science we define its influence The former problem is difficult enough but not insuperable the latter is not likely to be solved in our day

Obituary

MR SPENCER LE M MOORE

MR SPENCER LE MARCHANT MOORE, who died on Mar 14 last at the age of eighty years, joined the staff of the Herbarium at the Royal Gardens, Kew, in 1872, on leaving University College, where he gained the gold medal for botany Few young men have had the opportunity of training in so brilliant a school of systematists as Kew then offered Joseph Hooker was director, Daniel Oliver was in charge of the herbarium with J G Baker as his second, and George Bentham was in daily attendance, cooperating with Hooker on the "Genera Plantarum", the greatest classic of plant taxonomy Moore, who was about twenty one years of age, quickly got to work Between 1875 and 1880 he contributed a number of papers to the *Journal of Botany*, partly in co operation with J G Baker, on collections from North China, tropical Africa, and the Mascarene Islands, and on various genera of Orchids and Acanthaceæ In 1877 appeared, in the same *Journal*, the first of his "Alabastra diversa", a series of descriptions and critical notes bearing on genera and species of flowering plants, which, except for a long break from 1880 to 1899, continued almost yearly up to 1929 From 1877 until 1879 he assisted Henry Trimen in the editorship of the *Journal*

Then came a break An unfortunate difference with Hooker led to Moore's resignation in 1880, and an attempt to obtain a post in the Department of Botany of the British Museum was unsuccessful During the ten years that followed, he turned his attention to plant cytology and a succession of papers entitled "Studies in Vegetable Biology" appeared under his name in the *Journal* of the Linnean Society They dealt with such subjects as continuity of protoplasm, effect of light on protoplasmic movement, and the nature of callus But he was a lone worker, his papers attracted little attention, and one feels that he had got out of his proper element However, in 1891 came an opportunity He joined as botanist a prospecting expedition to Matto Grosso, Brazil, and returned with a large collection, the elaboration of which, comprising many new genera and species, and a general account of the vegetation of the district, filled 250 pages of a volume of the Linnean Society s *Transactions* It was distinctly his *magnum opus* In 1894–96, he joined a small gold-seeking expedition to the interior of Western Australia, and his "Botanical Results and Observations on the Nature and Relations of the Desert Flora", also published by the Linnean Society, was a valuable contribution to the botany of a little known area

Then in 1898, Moore came to anchor in the Department of Botany of the British Museum as an 'unofficial assistant', and from then until the time of his death worked steadily on the Museum collections His interests lay chiefly with the families Compositæ and Acanthaceæ and the Australian flora But there were few families of Dicotyledons of which he had not a working knowledge, and the results of his work appeared in a continuous stream of critical descriptive papers In the preparation of accounts of important collections received at the Museum, the elaboration of the gamopetalous and apetalous Dicotyledons generally fell to his share Since William Fawcett's death in 1926 he had been helping towards the completion of the "Flora of Jamaica" He had finished the Compositæ and the greater part of the Rubiaceæ, when a paralytic stroke abruptly ended his work, in his eighty first year

Few botanists have left such a full record of critical taxonomic spade work, or have accumulated so extensive a knowledge of the minutiæ of the genera and species of flowering plants Spencer Moore's kindly personality and his invaluable help, always ungrudgingly given, will be greatly missed by his former colleagues at the Museum A B RENDLE

WE regret to record the death on Dec 19, at the age of eighty-nine years, of Dr C Willgerodt, extra-ordinary professor of chemistry at the University of Freiburg-im-Breisgau From the *Chemiker-Zeitung* we learn the following particulars of his career Born at Harlingerodt in 1841, the son of a farmer, Willgerodt was trained as a teacher and spent some years teaching in an elementary school before turning his attention to scientific work At the Polytechnic at Brunswick, he began to study zoology, but in his twenty-eighth year he moved to Berlin, where, under the inspiring influence of A W von Hofmann, he devoted his whole time to chemistry Two years later he accepted a post as chemist in a colour factory at Elberfeld, and shortly afterwards he became manager of a factory at Opladen Feeling, however, a desire for further study, he gave up his post and entered the University of Freiburg, where, after graduation, he was appointed to the teaching staff Willgerodt remained at Freiburg for the remainder of his life In 1896 he was appointed director of the Technological Institute, and in 1915 extraordinary professor of inorganic chemistry and technology Willgerodt published numerous original papers on organic chemistry, the best known of which deal with the interaction of chloroform, acetone, and caustic alkalis and with the iodoso- and iodoxy-derivatives of benzene

---

WE regret to announce the following deaths

Dr J C Hemmeter, professor of physiology and clinical medicine in the University of Maryland, known for his work on the physiology and pathology of the intestines, on Feb 25, aged sixty-seven years

Mr J G Millais, who was the author of many books on natural history and sport and was known for his excellent animal paintings, on Mar 24, aged sixty six years

Mr P P Quayle, physicist to the Phillips Cartridge Company of America and formerly an assistant in the Bureau of Standards, who was a recognised authority on ballistics, on Feb 21

Mr A J Turner, principal of the Victoria Jubilee Technical Institute, Matunga, Bombay, author of a number of papers on chemistry, on Mar 15, aged fifty six years

News and Views.

Presidents of the Chemical Society, in their annual addresses, customarily exercise choice of subject between the affairs of the society and matters of purely scientific interest. Prof. J. F. Thorpe, who was this year in the unique position of presiding for the third time in succession over the annual general meeting, divided his address, delivered on Mar. 26, into two parts. In the first part he commented on the Society's progress during the decade in which he has been in intimate touch with its work as treasurer and as president; in the second, which was not delivered at the meeting but will be published in the *Journal*, he will discuss the results obtained at the Imperial College of Science and Technology in researches on the chemistry of the glutaconic acids and on the modified strain theory of carbon ring formation. The retrospect dealt first with the scheme for providing a central building to house various societies connected with mining, metallurgy, and chemistry, and referred to the constitution of an association and its registration under Section 19 of the Companies Act, 1929, whereby powers practically equivalent to those usually granted in a Royal Charter have been secured. The association may make no profits, neither may it give any bonus or distribute any money to its members, hence any excess of income over expenditure will lead to a corresponding reduction in the rents paid by the constituent bodies. After careful consideration, a proposal to house the association in the building which has just been erected by Anglo Properties, Ltd., adjacent to the Imperial Chemical Industries building at Millbank, has been rejected, and recourse has been had to the site originally proposed, which is adjacent to Abbey House, Westminster. The sum of £100,000 in cash must be paid by June 24 next to purchase the lease and sub-leases. An appeal to the Treasury has failed to secure assistance, and a similar appeal to the Pilgrim Trust has met with no response.

Abstracts of chemical literature are responsible for an increasingly severe tax on the financial resources of the two societies—the Chemical Society and the Society of Chemical Industry—by which, through the Bureau of Chemical Abstracts, *British Chemical Abstracts* is published. Prof. Thorpe's presidential address referred to the fluctuations in income and expenditure which arise from this and other causes, and advocated the immediate formation of a reserve fund. Since 1921, the membership of the Chemical Society has remained almost constant at about 3900; during the same period receipts from the sale of publications have been nearly doubled, but the cost of publications has largely increased. In advocating co-operation between *British* and *American Chemical Abstracts* in order to minimise waste of money and energy, Prof. Thorpe said that the decennial index afforded an opportunity for collaboration, and suggested as a first measure the quinquennial publication of a joint index giving references to both sets of abstracts. In an alternative scheme, the cost of the abstracts could be spread over a wider field. Such a publication ought to be of interest to all chemists, and ought to be supported by all chemists, yet some 4000 British chemists are not members of either of the two societies which maintain the service. Institutions desiring to avoid the possibility of curtailment of chemical publication, owing to lack of funds, might be willing to pay to the Bureau of Abstracts a sum per head of all those of its members who do not belong either to the Chemical Society or to the Society of Chemical Industry; every member would then be entitled to receive a copy of the *Abstracts*, and the institutions could have the right to appoint a representative to serve on the Bureau. Before concluding his address and inviting Dr. M. A. Whiteley to unveil a portrait of the first president, Thomas Graham, Prof. Thorpe referred to the prolongation of the life of the Dyestuffs Act, and emphasised its influence on scientific research.

The Imperial Institute has been relieved of its most pressing financial anxieties by the munificent gift by Mr. Benjamin Drage of £36,000, which is to be paid in the course of the next few years and is to be applied to the maintenance and improvement of the Institute. The offer has been made to the Empire Marketing Board, and has been accepted by its chairman, Mr. J. H. Thomas. The Imperial Institute was greatly aided by the annual donation of £5000 by the late Lord Cowdray; the cessation of that contribution and the financial embarrassment of some of the leading supporters among the Overseas Dominions have recently threatened some of the work of the Institute. Mr. Drage's gift will assure its development. The Institute has recently held an exhibition explanatory of the mineral resources of the British Empire, which has shown a happy combination of picturesque dioramas that illustrate graphically the mining operations, collections of the ores and minerals, and statistical diagrams of Imperial and world production and reserves. Mr. Drage has made his noble contribution from his realisation of the value of the Imperial Institute as a national centre for education in the economic resources of the Empire. Sir William Furse is to be congratulated on the growth of public confidence in the usefulness of the Institute, of which Mr. Drage's donation is striking evidence.

In his Friday evening discourse delivered at the Royal Institution on Mar. 27, Lord Rutherford discussed helium and its properties. He opened with a résumé of the dramatic history of the discovery of this element. In 1903 Ramsay and Soddy found that helium was produced by the transformation of radium and, as a result of a series of researches, Rutherford showed that the α-particles which are ejected with great velocity from radioactive atoms were identical with helium nuclei. It is probable that the greater part, if not all, of the helium found in the earth and in the natural gases escaping from the earth owes its origin to the α-particles expelled from the radioactive elements during their transformation in the earth's crust. It now seems clear that the helium nucleus of resultant charge 2 is remarkably stable

and is in some way built up by the combination of 4 protons and 2 electrons The loss of mass in this combination shows that a very large amount of energy, probably in the form of penetrating gamma rays, is emitted during the process It can be calculated that the energy released in the formation of one pound of helium from hydrogen corresponds to the energy liberated in the complete combustion of 10,000 tons of coal There can be no doubt that helium is formed from hydrogen under some, as yet unknown, conditions in the stellar system However, it has not yet been found possible to produce helium from hydrogen under laboratory conditions

IN 1914, Lord Rutherford continued, Sir Richard Threlfall suggested to the Board of Inventions of the Admiralty that, on account of its lightness and non inflammability, helium might prove of great service for balloons and airships Prof J C McLennan of the University of Toronto, was asked to initiate experiments to see whether helium could be separated in quantity from the natural gases escaping from the earth in certain districts of Canada which were known to contain about one per cent of helium by volume Arrangements were made on a semi commercial scale to purify the helium by liquefying the methane and other gases present The impure helium was concentrated in the non liquefying portion In this way, many thousands of cubic feet of helium were prepared and transported in cylinders at high pressure About the same time, the Bureau of Mines of the U S A began similar experiments on a large scale, using the natural gases of Texas which were rich in helium Large quantities of helium were separated by liquefaction methods and the cost of the helium was found to be sufficiently low to use it in airships in the place of hydrogen The commercial prospects of the use of helium in airships and other purposes has led to a search for rich concentrations of helium While most natural gases contain less than one per cent of helium, a rich mixture has been recently found in Colorado by boring, which contains more than 7 per cent of helium by volume A plant has been installed which deals with about 600,000 cubic feet of gas per day This should give an annual production of helium of 12 million cubic feet It may be possible that similar rich concentrations may be found on the eastern slopes of the Rocky Mountains in Canada A small gas field was found a few years ago not far from Toronto which had a content of 0 8 per cent helium The rights of these wells have been secured for the University of Toronto in order to have an ample supply of helium for cryogenic experiments in its laboratories

MEMBERS of university staffs are familiar with the inconvenience which results when summaries of theses and dissertations prepared under their supervision or under that of their colleagues are not made and so kept as to be readily accessible Such a collection of abstracts with particulars of publications by members of the University of Leeds, for the session 1929–1930, has recently been published Besides proving a useful reference book within the University, it should be welcomed elsewhere as a demonstration of the manner in which one of the primary functions of a university—the acquisition of new knowledge—is being performed The pamphlet of fifty four pages covers the work done in the faculties of arts, science, medicine, and technology One of the theses describes the results of a topographical study undertaken in order to test the historicity of a group of Icelandic sagas, another concerns the phonology of the old Northumbrian texts The chemical section contains abstracts of theses on such varied subjects as the atomic weight of silicon, the molecular weight of carbon monoxide, aromatic substitution, and catalytic activity Other work carried out included studies on tobacco mosaic, the growth of *Pinus sylvestris*, biochemical oxidation, the chemical aspects of immunity, experimental carcinogenesis the behaviour of electrons, the properties of reinforced concrete beams, the ventilating properties of fabrics, the physico chemical properties of wool fat, the preparation of phthalazine derivatives, and the emission of infra red radiation during gaseous explosion

WE have, from time to time, directed attention, in our columns devoted to "Research Items", to the publications of the Bernice P Bishop Museum of Honolulu of which the primary object is the elucidation of the ethnological problems of the Pacific For some years the museum has added very considerably to our detailed knowledge of the cultures and physical characters of the inhabitants of Polynesia by the publication of the results of the Bayard Dominick Expedition Much of this material is still under examination, while other studies are forthcoming In the meantime, an interesting and intentionally provocative analysis by E S Craighill Handy ("The Problem of Polynesian Origins", *Occasional Papers*, No 8, Bernice P Bishop Museum) offers a suggestion on the complicated question of Polynesian Asiatic relationships We will not attempt here to follow Mr Handy in the details of his argument, in which he traces the various cultural and ethnical influences from Asia which have penetrated Polynesia in prehistoric, Brahmanical, and Buddhist times, but Mr Handy's views on the means by which they were carried to Polynesia are interesting He suggests that the habit of thinking of Polynesian migrations in canoes should be abandoned Almost certainly, the later Malaysians and Asiatics started their voyages, which were probably accidental, in ships The effective agent was the strong current which runs between Luzon and Formosa, so strong that "any sailing ship sucked into it is flung out towards Micronesia" It may not be without interest to recall that the late Sir Henry Howorth, shortly before his death, suggested the derivation of certain cultural elements in Polynesia from Tibet, the casual castaway ship being made accountable for their introduction into Polynesia

PROF ELLIOT SMITH'S Henderson Trust Lecture on "The Significance of Peking Man" (Oliver and Boyd, pp 20, 6*d*), from which we published extracts in NATURE, Feb 7, p 202, pays a well deserved tribute

to the vision and perseverance of Dr Andersson and Dr Davidson Black, by which the existence of early man in China has been established Dr Black's courageous identification of a new human genus on the evidence of the tooth discovered by Dr Bohlin at Chou Kou Tien in 1927 is now fully vindicated Prof Elliot Smith's survey of the course of events, from the first tentative suggestion of the human or anthropoid character of the tooth bought in Peking in 1903, leading up to the final discoveries, is a valuable record for the future historian of scientific discovery Not the least of its merits is the credit given the Chinese authorities for their enlightened support—a support which would, no doubt, have been even more helpful had it not been for the unfortunate course of political events In the circumstances, it was to be expected that the actual specimens should remain in Peking, and that those who wish to study them at first hand must visit China The excellent series of photographs, however, with which Prof Elliot Smith has illustrated his lecture in its published form, gives the reader an opportunity of judging for himself its many remarkable features Among these, the most striking is, perhaps, the remarkable thickness of the walls of the skull as compared with those of Piltdown man, to which the author refers A comparative series of jaws brings out the resemblance between those found at Chou Kou Tien in 1927 and the chimpanzoid jaw of Piltdown As Prof Elliot Smith says, these jaws have now settled a controversy which had lasted for sixteen years

ONE of the chief desiderata of the Zoological Department of the British Museum (Natural History) has recently been supplied by a gift from His Highness the Nawab Sahib of Junagadh of complete male and female specimens of the Indian lion the specimens comprising perfect skins, skulls, and skeletons of two adult animals The skins have been placed in the study collection The Department of Entomology of the Museum has been fortunate in securing the collection of Hesperiidæ (Skipper butterflies) formed by M René Oberthur, of Rennes, consisting approximately of 60,000 specimens from all parts of the world The bulk of the present acquisition was originally part of the great collection of butterflies formed by the late M Charles Oberthur, the greater portion of which, amounting to nearly 800,000 specimens, came into the possession of the Museum in 1897 But to this section of his brother's collection M René Oberthur was able to add, after he had acquired it, the collection of Hesperiidæ formed by M Mabille, who was for many years the leading authority on the group The Department of Geology has received four specimens of the primitive ichthyosaur, *Mixosaurus*, found in the Middle Trias of Edge Island by Mr N L Falcon during an expedition to Spitsbergen in 1927 Two specimens are parts of jaws, another is part of a limb, but the fourth is the almost entire vertebral column, about five feet long The condition of the vertebræ is excellent, and all the neural spines are preserved and clearly indicate the presence of a small tail fin Miss A Lorrain Smith has presented to the Department of Botany 646 drawings of fungi, lichens, and Mycetozoa made by John Templeton (1766–1825), a well known Irish botanist The drawings were given to Miss Lorrain Smith by Dr Howard Kelly, of the United States, and his letter of gift, stating that the collection "should return home, where it can be studied and where it will serve to bring more credit to its author" than would be possible in the United States, is included

IN modern practice, the heat developed in large electric machines and devices limits the load they can carry and therefore their rating Elaborate methods of keeping them cool are adopted and they are sometimes placed in the open air In Great Britain there are many outdoor substations, and this practice is rapidly increasing Another interesting trend of development is to put them in various kinds of gases and liquids so as to facilitate their cooling Transformer coils, for example, are often placed in nitrogen and rotating machinery in hydrogen Many kinds of switchgear are placed in oil or gum In the *Westinghouse International* for January, a 9375 kilovolt ampere turbo generator is described, the rotor of which has been running successfully in hydrogen for six months, despite the fact that it has a projecting shaft It is common practice to run synchronous condensers which have no projecting shaft in hydrogen It has been found experimentally that using hydrogen instead of air increases the rating of the machine by at least 25 per cent In addition, the efficiency is found to be 1 per cent greater, also, there is no need to guard against damage being done to the insulation by effects due to corona discharges Since the machine is hermetically sealed, it can be placed out of doors The hydrogen pressure is kept slightly above the atmospheric pressure, so that the leakage, which tests show to be extremely small, is outwards In case of any abnormal conditions occurring, automatic signals attract the operator's attention

THE Council of the London Mathematical Society has decided on an extension of the scheme, which was started six years ago, of devoting two of the meetings in each session to a lecture It has now been decided to devote an occasional meeting to a set discussion on recent advances in a selected branch of mathematics The first of these discussions will take place at the meeting on April 23 at 5 P.M. at Burlington House The discussion, which will be on "Recent Work in the Additive Theory of Numbers", will be opened by Prof G H Hardy, he will be followed by Mr E Maitland Wright on "New Partition Problems", Mr A E Ingham on "The Method of Brun and the Theorem of Schnirelmann", and Dr A E Western on "Computative Work connected with Waring's Problem" It is hoped that Prof L J Mordell, Mr S D Chowla, Dr T Estermann, and Prof J E Littlewood will also take part in the discussion The second lecture of the session will be given by Prof J E Lennard-Jones at the meeting on May 14 Members of other scientific societies who may be interested are invited to attend these meetings

In recent years, many aquatic birds have shown a new spirit of colonisation in Great Britain The spread of more than half a dozen species of wild ducks, especially in Scotland, has been remarkable Sharing with the ducks in this great advance movement, and we refer again particularly to Scotland, has been the great crested grebe But there is evidence that the breeding range of this species is altering in England also, and, if this be so, the sooner exact information about the past and present detailed distribution is collected the better For with such a firm basis of fact, future movements may be recorded with accuracy and perhaps some of the factors concerned in so general a movement may be elucidated Naturalists, therefore, would be doing good work if they contributed information to the "Great Crested Grebe Enquiry" of T H Harrisson and P A D Hollom The investigation aims at forming a census of great crested grebes for the whole of Great Britain, and is supported by *British Birds* (Feb 1931) Schedules to be filled in with desirable data may be obtained from Mr Harrisson, at Pembroke College, Cambridge

The value of red squill powder in the destruction of rats is becoming increasingly recognised When experiments were carried out in the Zoological Gardens in London some years ago, it was found that the liquid preparation of red squill (a liliaceous plant known also as scilla and sea onion, *Urginea maritima*) was more trustworthy than powder mixtures Since 1923, however, the U S Department of Agriculture has been experimenting with the powdered forms, and it has been found that a powder of maximum toxicity can be obtained by drying the sliced bulbs at a constant temperature of 80° C Thus the greatest difficulty in the use of red squill, irregularity of results, has been overcome, and the poison has become the most widely used against rats in the United States It is greatly in its favour that this rat poison is relatively harmless to human beings and domestic animals, indeed, in field tests, prairie dogs and pocket gophers refused to eat the red squill baits and in most cases cats, dogs, chickens, pigeons, and pigs either refused to eat poisoned foods or, having eaten, promptly vomited them One of the authors of the new U S Dept Agriculture *Leaflet* 65, "Red Squill Powder and Rat Control", himself swallowed 15 grain and 40 grain doses of a toxic red squill powder without untoward results

Two recent *Botany Leaflets*, Nos 15 and 16, received from the Field Museum of Natural History, Chicago, appear to be almost models of their kind No 15, on "Spices and Condiments", by James B McNair, whilst full of information, has a wide general appeal, because the history and romance of these plant products are always kept in view Writing for the New World, the author emphasises the fact that most of the spices used by man have had their home in the tropics of Asia, whence they have spread all over the globe, the value of all spices shipped directly to the United States averages about twelve million dollars annually *Leaflet* No 16, "Fifty Common Plant Galls of the Chicago Area", by Carl F Gronemann, is also extremely attractive A brief introduction is well calculated to arouse the reader's interest All the galls described are clearly illustrated, and although their number is so small, probably any Chicago reader could soon find a few of them near his home Interest once thus aroused, plenty of references are supplied to help the reader to further knowledge in a little-studied field It is doubtful whether in strenuous northern America, especially the eastern United States, the amateur naturalist has flourished as he has under English conditions, and these leaflets should do much to encourage the development of the naturalist in the strenuous industrial centre served by the Museum

The National Smoke Abatement Society has issued No 1 of its second volume (23 King Street, Manchester, 1*s* quarterly), which shows how the problem of atmospheric pollution is being handled in different parts of Great Britain New ground is being broken by the West Riding of Yorkshire Regional Smoke Abatement Committee in setting up a scheme for training and certification of stokers and boiler attendants In its first year, candidates from eleven centres are already expected to sit for examination, and there are indications of more next year It is hoped that improved training will raise the status of the fireman, and by more intelligent operation, promote not only efficiency and economy, but also reduce the nuisance which is so great in the textile areas The journal reveals great efforts of smoke abatement reformers, but the difficulty is to secure the active co operation of the smoke producers, both domestic and industrial

The United States National Museum, the expenses of which have been provided by Congress since 1877, cost during the year ending June 30, 1930, a sum of 762,514 dollars, 14,490 dollars above that of the preceding year More than half a million specimens were added to the collections, including a great ball of crystal 12⅞ inches in diameter and weighing 106¾ pounds, believed to be the largest perfect crystal sphere in existence The specimens now covered in the museum catalogues number 12½ millions, of which more than 9 millions belong to the Department of Biology, and 2 millions to Geology The annual attendance remains very high, the visitors approaching the two million mark, and it is remarkable that in the course of four years the annual number of visitors to the Arts and Industries Section, which now stands at 863,000, should have increased by half a million, while other sections show relatively small increases

The United States Geological Survey has republished a general introduction to the Coalfields of the United States and a chapter on the Coalfields of Ohio (*U S Geol Surv Prof Pap* 100), which were first published in 1917. At that time it was planned to publish similar descriptions of the coalfields of the various States, this plan has now been abandoned, but it has been considered worth while to republish the two chapters in question The general description of the coalfields by Mr Campbell occupies some thirty three pages, whilst that of the

coalfields of Ohio by Mr Bownocker occupies some sixty-one pages, for the purposes of the general student of the distribution of the world's coalfields, the former is undoubtedly of far greater importance, and the United States Geological Survey is to be congratulated upon its decision to republish this information and thus render it more readily accessible

THE spontaneous combustion of coal is a source of trouble to those concerned with the winning, transport, and storage of coal At air temperature, oxygen may be absorbed, causing a rise in temperature, but after a time, smouldering begins The Safety in Mines Research Board has issued a report (No 63) of an investigation by H E Newall and F S Sinnatt on the "Propagation of Combustion in Powdered Coal" This smouldering of coal dust can be propagated at temperatures above 130° at a speed which depends on conditions, but can be so low as 5 in per hour It was shown that appreciable quantities of hydrocyanic acid were evolved on combustion at 500°-600°, which suggests the existence of an additional and unsuspected hazard associated with spontaneous combustion

IN the December issue of the *Quarterly Review of Biology* is the fifth annual report on the cost of biological books This deals with the books received during the year 1930 The biological books published by the United States Government stand lowest in the comparative list of prices France continues to produce the cheapest commercially published scientific books, costing on the average, at 0 47 cent per page, less than half as much as those of any other country, while there is a continued increase in the prices of German books, which average 1 82 cents per page, being far above that of any other group except the English American books, in the cost of which (at 1 91 cents per page) are included transportation charges and tariff The cost of English biological books (1 13 cents per page) decreased slightly as compared with 1929

WATSON'S *Microscope Record* for January (No 22) contains useful practical articles on "Microscopical Methods for Mycetozoa", by J M Coon, and on "Cements and Finishes for Microscopical Preparations", by W D Grier C H Oakden continues his notes on early photomicrographers Details are given of contributions by, among others, Fox Talbot (1839), Hogg (1841), and Diamond, the first secretary of the Photographic Society (now the Royal Photographic Society) Draper, who in 1840 made the first astronomical photograph of the moon, between 1851 and 1856 took several daguerreotypes of microscopical objects Donne in 1884 issued an "Atlas d'anatomie microscopique", containing no less than eighty photomicrographs printed from daguerreotype plates etched with hydrochloric acid The plates, being of very soft metal, were useless by the time fifty impressions had been taken This "Atlas" is the first book of photomicrographs published

THE Daniel-Pidgeon award for 1931 of the Geological Society of London has been made to Mr W Q Kennedy, who proposes to investigate certain porphyritic and non-porphyritic basic intrusions of composite character in the Tertiary province of the west of Scotland

AT the annual general meeting of the Ray Society on Mar 20, the following officers were re elected *President* Prof W C M'Intosh, *Treasurer* Sir Sidney F Harmer, *Secretary* Dr W T Calman Mr D J Scourfield was elected a vice president, and Prof F Balfour Browne and Mr Charles Oldham were elected new members of Council It was announced that the first volume of Dr Gurney's monograph on "British Copepoda" is in the press and will form the Ray Society's issue for 1931 The Council appeals for further support to enable the Society to continue its work of publishing natural history books which otherwise would be unlikely to find means of publication

THE Glass Manufacturers' Federation has arranged an exhibition of British glass and glassware to be held in the exhibition hall of Messrs Selfridge and Co, Ltd Oxford Street, London, on April 13-18 Among the ten sections into which the exhibition will be divided are safety and 'health' glass, chemical scientific, laboratory, medical, and machine glassware, gauge glass glass tubing and rods, and neon signs optical glass lenses, and lighthouse glass, electric lamp bulbs for lighting and scientific purposes Among the demonstrations which have been arranged are glass blowing, 'health' glass, invisible rays, and glass eye making

AN exhibition is being held in the Czechoslovak National Museum, Prague, of the works of the great seventeenth century astronomers, Johann Kepler and Tycho Brahe Though neither was a native of Bohemia, each spent the most important and fruitful period of his life in Prague Each, too, was in turn Astronomer Royal to Rudolph II, who made Prague a centre of art and learning Kepler was there during the years 1600 to 1612, and taught at the German university The exhibition contains material drawn from within the borders of Czechoslovakia, especially from the libraries of Strahov Monastery and the University of Prague, the State Observatory, and the private collection of the Fric family

THE preliminary programme of the congress of the Royal Institute of Public Health to be held at Frankfurt on Main on May 19-24, has recently been issued Amongst much information, including a preliminary itinerary, is the list of sectional presidents They are Section (1), State medicine and municipal hygiene, Lord Moynihan and Prof M Taute, Section (2), architecture, housing, and town planning, Prof Patrick Abercrombie and Dr O Weigert, Section (3), industrial hygiene, Viscount Leverhulme and Dr Arthur von Weinberg, Section (4), women and children and the public health, Viscountess Erleigh and Prof H von Mettenheim, Section (5), tuberculosis, Dr David Davies and Prof L Brauer, Section (6), pathology, bacteriology, and biochemistry, Prof Theodore Shennan and Prof W Kolle

IN his presidential address on Mar 22 to the Glasgow Archæological Society, Mr Ludovic Mann described

some recent discoveries in the west of Scotland. Many of the relics were exhibited. A notable find was that of a Roman warrior buried, after cremation, on the Wigtownshire shore, associated with three Roman pottery vessels, two of *terra sigillata*; two iron spearheads; an iron sword; some iron fragments in the nature of plating; a bronze ring; an iron ring containing an intaglio of pale green chalcedony engraved with the figure of a female, robed and holding in her left arm what appears to be a palm branch.

A short handy list (B 7) of second-hand books on botany, herbals and medicinal plants, gardens and gardening, fruits and fruit culture, trees and shrubs, agriculture and husbandry, has been issued by Messrs. Francis Edwards, Ltd., 83 High Street, Marylebone, W.1.

Messrs. W. H. Robinson, Ltd., 16 Pall Mall, S.W.1, have just issued a "Catalogue of Rare Books", No. 32. Most of the books listed are of a general character, but there are some of scientific interest, for example the first edition of Malthus's "An Essay on the Principle of Population, as it affects the future improvement of Society"; several volumes of the Hakluyt Society, and a manuscript in 3 vols. of lectures on chemistry by Prof. Joseph Black, of Edinburgh.

Applications are invited for the following appointments, on or before the dates mentioned:—A handicraft instructor at the Anerley Residential School—The Education Officer (S.S.6), County Hall, Westminster Bridge, S.E.1 (April 11). A junior lecturer in commerce in the University of Liverpool—The Registrar, The University, Liverpool (April 13). A lecturer in education in the University of Sheffield—The Registrar, The University, Sheffield (April 18). A junior scientific officer under the directorate of scientific research of the Air Ministry, for research in connexion with electrical equipment, especially with reference to electrical ignition apparatus—The Chief Superintendent, Royal Aircraft Establishment, South Farnborough, Hants (April 18). A probationer naturalist on the scientific staff of the Fishery Board for Scotland—The Secretary, Fishery Board for Scotland, 101 George Street, Edinburgh (April 20). An assistant in the Brighton Public Museum with a knowledge of ornithology and taxidermy—The Director, North Gate House, Church Street, Brighton (April 27). An advanced studentship in education in the University of Manchester—The Registrar, The University, Manchester (May 1). An additional assistant pathologist in the Public Health Department of the Shanghai Municipal Council—John Pook and Co., 68 Fenchurch Street, E.C.3.

Our Astronomical Column

Early Images of Pluto on Flagstaff Plates.—*Harvard Card*, No. 148, reports that images of Pluto have been detected on two plates taken at the Lowell Observatory in the spring of 1915. That was the year in which Prof. P. Lowell's "Memoir on the Trans-Neptunian Planet" was published, and it is quite likely that he examined these plates himself; they were presumably taken specially for the search. It is much to be lamented that the images were not detected at the time, as Prof. Lowell would then have been cheered, before his death, by knowledge that his prediction was successful. Incidentally, the number of pre-discovery images of Pluto that were undetected at the time (eleven are now known) emphasises the skill and alertness of Mr. Tombaugh in making the discovery so promptly after inspection of the plates of January 1930. Dr. Bower has corrected the orbit of Pluto by computing the planetary perturbations, and gives the following residuals (Observed—Calculated) for the earliest three positions:

				R.A.	Decl.
1914	Jan.	23	Königstuhl	+2·9″	+0·4″
1915	Mar.	19	Flagstaff	+3·0	−2·7
„	April	7	„	+3·8	4·8

He asks that any observers who possess plates that might contain images of Pluto should send him the dates of exposure; he would then calculate the perturbations and send an accurate position to assist in the search upon the plates. His address is the Students' Observatory, Berkeley, California.

A Very Distant Spiral Nebula.—A *Daily Science Bulletin* issued by Science Service, Washington, D.C., dated Feb. 25, announces that M. L. Humason has photographed with the 100-inch reflector at Mount Wilson the spectrum of a very faint nebula discovered by W. H. Christie; its position in the sky is not stated. The spectrum shows a shift of the lines towards the red, corresponding to a recession of 17,600 km./sec., and an estimated distance of 120 million light years. This is by far the most distant nebula the distance of which can be regarded as 'measured', but it will be remembered that when Dr. Hubble published his determination of the distances of the Andromeda nebula and Messier 33 as nearly a million light years, he estimated that the faintest nebulæ that could be reached with the 100-inch were distant about 150 million light years. The estimate of distance derived from the spectral shift is independent of the view taken as to the reality of the recessional movement. Prof. A. Einstein, the Mount Wilson astronomers, Sir James Jeans, and others regard this movement as only apparent, arising from the properties of the four-dimensional space-time continuum; but Prof. de Sitter (supported to some extent by Sir Arthur Eddington) considers that the recession is really going on. Prof. Einstein is now at Mount Wilson, and naturally he is following this investigation with great interest.

Heights and Diameters of Lunar Craters.—The *B.A.A. Jour.* for January contains a statistical paper by T. L. MacDonald, in which he studies the altitudes of the walls surrounding the craters, measured both from the external plain and from the crater floor, and correlates them with the diameters. Detailed measurements are given for about two hundred formations. The graphs that are given show that the height varies approximately as the square root of the diameter, so that the plotted points lie on a parabola. To a diameter of 84 km. corresponds a height of 4·4 km., and to 24 km. corresponds 2·8 km. Craters in the region between Tycho and the south pole (which the author calls the continental region) are unusually high for their diameter. A drawing of an ideal lunar crater (in which the vertical scale is much larger than the horizontal one) shows that the slope on the inside of the crater walls is much steeper than on the outside.

Research Items.

Folk-memory in Crete—The contents of vol 41, pt 1, of *Folk-Lore* include the presidential address to the Folklore Society by Prof R M Dawkins at the close of his term of office It illustrates the general principles of the evidential value of folk memory in application to a specific area in which it is possible to check tradition by bringing it into relation with historical records There is no popular tradition now alive in Crete which reaches back to Minoan times, and in fact it does not go back earlier than the name Hellen The preservation of place names and, indeed, of the language—a popular form banned by literature and learning—is in itself an effort of folk memory But until recently the name Hellen meant pagan and the place names which preserved a long tradition have been obliterated by recent changes Of Christian history, a memory, if mistaken, is enshrined in the tomb of Caiaphas Of Byzantine history there is little to show One tradition, though false, preserved a record of the voyage of Eudocia in 443 A D, while another, entirely false, related to a Byzantine lady of the ninth century Of the Arab occupation there were no stories, but the story of the Twelve Archons' refers to the Byzantine reorganisation of Cretan society from Constantinople after the reconquest The ballads and legends of Digenis, a hero of the struggle against the Saracens on the Asiatic frontier, are also referred to Byzantium The raids of pirates made considerable impression on the popular mind, and the Venetian supremacy was also remembered, but it is with the Turkish occupation that popular memory really begins, and to it popular tradition and legend predominantly belong

A Ritual Use of Rock Paintings in Tanganyika—In the March issue of *Man*, which is devoted entirely to Africa, Mr A T Culwick describes a ritual at Bahi In certain rock shelters are rock paintings about which Wagogo tradition relates that Wamia, who was driven out by their earliest ancestor Kiman chambogo, and Amankara made them, when they sacrificed cows, using the fat of the victims to make the lines Now, therefore, the Wagogo, although they know nothing of the meaning of the paintings, during a drought go to these rock shelters, which they regard as sacred, and *tambika* there—that is, offer up a special form of sacrifice in which the entrails are taken out of the victim and thrown at the sacred object The fat of the animal is used to brush over the painting, following the lines drawn by Wamia The present Wamia tribe, who are said to have been an offshoot of the Masai, have funeral rites of an unusual type When a distinguished man or woman dies, a rock is *tambika'd* All the elders assemble, bringing with them a black robe, a black sheep, and black cow They drink beer, which they then spit out on the rock The fat of the sacrificed animals is melted and with it a picture of the dead man is drawn on the rock with some of his personal possessions, such as cattle, gourds, pestles and mortar, ornaments, etc The pictures are then covered with branches and all the people of the village are called for a feast and to drink beer After this, the elders pray to the deceased, asking for rain in return for their presents The entrails, with the black robe and some tobacco, are left at the foot of the rock A medicine man is always represented as a snake

Iodine Supply and Goitre—Investigations undertaken in the United States, Switzerland, and New Zealand indicate that there is a correlation between the level of iodine intake and the prevalence of endemic goitre In the same three countries, it is reported that the administration of iodine in goitre areas has been followed by a marked decrease in the incidence of the disease In England, the incidence of goitre among school children aged 13 14 years varies, in rural areas, from 0 4 per cent in Essex to 24 5 per cent in Somerset, and in towns from 0 1 per cent in Middlesbrough to 17 2 per cent in Preston In view of these differences, Dr J B Orr has undertaken a survey of the iodine content of foodstuffs in representative areas (Medical Research Council, *Special Rep Series*, No 154) The substances selected for analysis were soils and pastures, milk and eggs, all from the same farms and fields so far as possible, locally grown cabbages and potatoes, blood from local sheep and their thyroid glands The results obtained are inconclusive The iodine supply, as judged by the content of milk, eggs, and cabbage, is higher in the Scottish area, which is known to be goitre free, than in the English counties, where goitre is to a greater or less extent endemic On the other hand, there is no indication whatever of any definite difference between those areas in England with a low goitre incidence and those reputed to have a high goitre incidence

Life of the Spider A notable contribution to our knowledge of the biology of spiders has been made by Dr P Bonnet (*Bull Soc Nat Hist, Toulouse*, **59**, 237 700, 1930) In seven years, 1598 spiders of ten different species have lived under his care and no less than 522 have been raised from the egg to the adult This has enabled him to show that the number of moults during growth—4 to 22—depends only on the size of the spider, while the time between two moults depends more on the temperature and food supply than on age He describes a complex mechanism for the autotomy of injured limbs and shows that this cannot always be an involuntary reflex act Regenerated limbs require three moults to attain their normal size, the process of such regeneration is also described fully Some of his spiders achieved the regeneration of all eight legs simultaneously

Craniology of the Dog T Marchlewski (*Bull Internat Acad Polon Sci et Lettres*, No 7 8, B 2, 1930) discusses the relationships between the diverse groups of breeds of dogs, and concludes there are three clearly defined types as shown by their skull characters The *Canis leineri* or greyhound group is a uniform group sharply distinct from all other groups of dogs The *C optimæ matris* group is less clearly defined, shows no definite affinities with the greyhound group, and is formed by the narrow headed, long snouted collie type and by another type represented by the Alsatian wolf dog The *C decumanus* type, the primitive hound or gun dog type, has a long cranial region and comparatively high crested skull, narrow cranium and moderately wide forehead, and moderately long facial region This seems to be the type from which have been gradually evolved, with the influence of crosses of the greyhound and the collie type, the highly bred types of pointers

A New Mounting Medium—G D Hanna (*Jour R Micr Soc*, vol 50, pt 4, 1930) describes under the name "Hyrax"—a derivative of naphthalene—a new mounting medium for microscopic preparations of diatoms It is a resin of pale straw colour, its refractive index is 1 82, and it is soluble in benzene, xylol, and some other organic solvents, which are

easily expelled from the mounted preparation, by gentle heat In slides exposed to sunlight, the medium darkens "to about the colour of old balsam", but in those kept in cabinets, the medium remains "practically water white"

Hatching of Insects – E K Sikes and V B Wigglesworth (*Quart Jour Micr Sci*, vol 74, pt 2, 1931) record observations on the hatching spines present on the embryonic cuticle of bugs and lice The mechanism of hatching is described for a flea, the meal worm, a grain moth (*Sitotroga*), *Lucilia*, the bed bug, and a louse (*Polyplax*), and the general mechanism of the hatching of insect eggs is discussed The embryo increases in size very rapidly before hatching by swallowing the amniotic fluid, and thus acquires a better purchase for its operations against the chorion In every case, the force employed to break open the egg appears to be muscular The swallowing of air may also play an important part in the emergence of the larva The authors devote particular attention to the first appearance of air in the tracheæ of the larva This occurs in three different ways —(1) the surface of the larva dries while still in the egg, and the tracheal system fills, before hatching, from the outside air, for example *Ceratophyllus*, *Tenebrio*, (2) the larva at the time of emergence is enclosed in a cuticle which retains a layer of fluid, so that air has access to the tracheæ only when this embryonic cuticle is shed, that is, after hatching, for example *Cimex*, *Polyplax*, (3) the tracheal system fills with gas while the larva is still bathed in the fluid contents of the egg that is, it fills with the gases which were in solution, for example, *Lucilia* and the grain moth It is suggested that the fluid in the tracheæ, which has passed in previously from the tissues, is absorbed by the osmotic pressure of the tissue fluids, and that, since this pressure is increased by muscular activity, air appears earliest in those insects which show the greatest activity while in the egg

Edible and Poisonous Fungi —It is with pleasure that we note the appearance of a third edition of "Edible and Poisonous Fungi" (*Bulletin* No 23, Ministry of Agriculture and Fisheries, London, 1930, 2*s* 6*d*) The volume has always been useful to the country person, giving him an element of security in gathering fungi for food purposes and doing much to eradicate the numerous superstitions which have been built up around poisonous toadstools The present edition has been improved by the substitution of more typical illustrations, and four more common species have been described There is little danger of the non technical mind confusing any of the edible species, with the possible exception of *Amanita rubescens*, which is probably not sufficiently distinct from the poisonous *A muscaria* The descriptions are lucid and a short glossary is given

Microchemical Recognition of Saponin in the Plant — Robert Fischer and his colleagues are developing a new technique for this purpose Their methods and results are described in the *Sitzungsberichte* of the Vienna Academy of Sciences, Abt I, vol 139, 1930, pp 321 354 Essentially the method consists in covering a section with a gelatin solution containing salt, at a definite *p*H, by addition of phosphate buffers, and mixed with defibrinated blood or washed red blood corpuscles before it has set The section must be completely covered by the gelatin, when, if saponin is present and diffuses out of the section, a clear region will be seen to develop around the section owing to its hæmolytic action By the different behaviour of saponins in gelatin at different *p*H, it is claimed that different types of saponin can be recognised Solanin is also recognised by the fact that it is put out of action by cholesterol, if the section is boiled in a solution of this substance, whilst the cholesterol solanin complex is apparently broken up and the solanin again released by treatment with boiling xylol The distribution of saponins in various Caryophyllaceæ and Solanaceæ is examined by these methods

Fossils of the Samana Range —An account of the palæontology and geology of the Samana Range in the North West Frontier Province of India has been prepared by Lieut Col L M Davies and others (*Palæont Indica*, N S, 15, 1-8, 1930) The range consists of a single anticline crossed by two faults The Jurassic is represented by beds which appear to be either Upper Bathonian or Lower Callovian, and perhaps by Upper Jurassic In the Cretaceous there is definite evidence for Neocomian and Albian horizons Lower Eocene beds are well represented and correspond to the Ranikot series The Jurassic and Gault Brachiopods are described by Miss H M Muir Wood, the Albian Echinoids by Miss E D Currie, the Albian Gasteropods and Lamellibranchs by L R Cox, the Neocomian and Albian Ammonoids by L F Spath Of the Lower Eocene fauna, the Foraminifera are described by L M Davies, the corals by Prof J W Gregory, and the Mollusca by L R Cox, who gives an account of the palæo geographical conditions of the period

The Banket of the Witwatersrand An important paper, stimulated by Dr L C Graton's recent advocacy of a hydro thermal origin for the gold deposits of the Rand, was read by Dr L Reinecke at the meeting of the Geological Society of South Africa on Dec 8, 1930, and will appear later in the Society's *Transactions* Dr Reinecke shows that the orientation of the pebble axes, the inclination of cross bedding, the arrangement of the conglomerate lenses, and the thinning and gradual decrease of grade size from north west to south east proves that the Main Reef Leader of the Far East Rand was laid down by currents flowing from the north west, and not, as Graton supposes, by wave action The Witwatersrand system also differs from marine formations in its lack of calcareous members The whole assemblage is shown to resemble in a very remarkable way that of the Siwalik system of northern India The evidence of its having been deposited by streams on the lower piedmont slopes and flood plains of a large river system appears to be quite conclusive Orogenic conditions resembled those which obtained during the deposition of the Siwaliks but the climate was wetter and colder on the Rand than in the sub Himalaya Dr Reinecke also records that he has been unable to find any relation between the distribution of gold in the reef and the folds, faults, or fractures that affect the system or the dykes that have intruded upon it, with the exception that in places certain zones of payability have been displaced by post ore faulting The hydro thermal hypothesis seems to be definitely untenable in the light of the evidence now presented

Quiet-day Magnetic Variation —In a paper in the March number of the *Proceedings of the Royal Society*, Prof S Chapman and Mr J M Stagg present an analysis of the variability of the quiet day diurnal magnetic variation for the stations at Eskdalemuir, Greenwich, Ebro, San Fernando, Batavia, and Mauritius The ranges of the variation change from day to day irregularly, but there is a definite correlation between the changes in different elements and at different stations, the correlation being greater the nearer the stations Very quiet days often occur in sequences of two or more, and there is also a tendency

for abnormalities of range to persist for several days The interpretations which are put upon the results—the labour of obtaining which has been, naturally, extremely heavy—is that there is both a world wide cause governing the changes, this being probably the conductivity of an upper atmospheric layer due to a solar ionising agency, and a regional cause, which may be a local irregular distribution of temperature and density in the upper atmosphere

Discontinuous Sorption by Porous Solids—During the past few years, considerable evidence has been collected by Prof A J Allmand to show that there is an essential discontinuity in the process of sorption of vapours by charcoal The isothermals (vapour pressure plotted against quantity of vapour which has passed into a condensed phase in conjunction with the absorbing body) show many small breaks which are considered not to be due to experimental error The present position with regard to this important question is reviewed by Prof Allmand and Mr Burrage in the March number of the *Proceedings of the Royal Society*, and in a very full examination of their own results in relation to those of other workers, it is concluded that no discrepancies arise Scrutiny of results published by others indeed shows some comparable inflections of curves Some new results are also presented in this paper for silica gel, which also contain evidence for discontinuity, and it is pointed out that there are theoretical reasons for expecting that it should occur The authors remark that the experimental results make it even clearer than before that only work with plane or relatively plane surfaces is likely to yield information of value about the fundamental adsorption process, a complex porous sorbent like charcoal being inapplicable for this purpose

Impact of Spheres—A series of investigations has recently been carried out by Dr J P Andrews on the impact of spheres (*Proc Phys Soc*, Jan 1, 1931 and earlier papers) Interest in the problems of impact dates back at least as far as Newton, who gave his law of restitution in the Scholium to his Laws of Motion Actual theories of impact centre for the most part round either the wave theory of Saint Venant or the pseudo statical theory of Hertz The subject has in the past aroused the interest of numerous investigators, few problems have the wide appeal that this possesses alike for the physicist the engineer, and the mathematician The most widely known of these investigations is undoubtedly the famous 'guillotine' series carried out by P G Tait and commemorated in the Guillotine Room of the Physical Laboratory at the University of Edinburgh The ordinary mathematical theory of elasticity, based on a linear connexion between the stress tensor and the strain tensor, is competent to give an opinion on phenomena conforming to its range of limitations, but it makes no pretensions of prognosticating any resulting permanent set, though it might adumbrate the nature of secondary phenomena In the experiments carried out by Andrews on metal spheres, it appears that the permanent set takes a shape suggestive of a lunar crater There is a distinct depression, with a rather uneven and somewhat curved floor, surrounded by a raised rim The phenomena had been previously observed by Sir C V Raman and other investigators The results derived from experiments with low velocity of impact substantiate Hertz's theory that the time of impact is inversely proportional to the fifth root of the velocity An empirical law is given for the duration of impact in other cases, and a hypothesis is framed to explain the various results The essential feature of the hypothesis is that the pressure is constant at all points of the deformed area; it affords an explanation in a region where the exact mathematical theory is inadequate.

Atomic Weights of Nitrogen and Silver—The atomic weight of nitrogen by the gravimetric method is intimately related to that of silver through the ratio Ag $AgNO_3$ More recent measurements of the limiting density of ammonia have given accurate values with respect to hydrogen, and other lines of evidence show that the value (referred to O as 16) is very nearly 14 008 (the oxygen standard is the isotopic mixture) Baxter and Greene in the February *Journal of the American Chemical Society* describe the determination of the ratio Ag NH_3, which with the ratio Ag NO_3 gives the ratio NH_3 NO_3 This, with the assumption of the H O ratio, makes possible the calculation of the atomic weight of nitrogen The principle of the method had been applied by Stas A weighed quantity of ammonia adsorbed on dehydrated chabazite was evaporated into dilute hydrochloric or hydrobromic acid until the acid was exactly neutralised The halogen content of the solution was then found by nephelometric comparison with the purest silver in the usual way Great precision in the neutralisation end point could be attained by using methyl red or litmus as indicator The ratio $NO_3/Ag = 0\ 57479$ was assumed The ratios Ag $NH_3 = 6\ 33401$ and NO_3 $NH_3 = 3\ 64073$ give $N = 14\ 0085$ (isotopic mixture of oxygen = 16) These numbers are not corrected for a very small amount of water in the ammonia, and on the whole the final outcome is regarded as valuable corroborative evidence that the atomic weight of nitrogen is very close to 14 008 If nitrogen is taken as 14 0078, the atomic weight of silver will be 107 879, whilst $N = 14\ 008$ gives $Ag = 107\ 880$ from the Ag NH_3 ratio and 107 879 from the Ag NO_3 ratio

Oxygen Films on Tungsten Langmuir and Villars in the February *Journal of the American Chemical Society* describe a method of studying the rate of loss of oxygen from an adsorbed film on tungsten, as well as of detecting its presence in a gas which consists in observing the effect on the electron emission of a tungsten filament, sensitised by the presence of a minute trace of cæsium vapour (10^{-6} mm) Under properly chosen conditions a monatomic oxygen film makes its presence known by increasing the emission a million fold By this method the heat of evaporation of oxygen from the adsorbed layer was calculated as 162 k cal per gram atom The method of preparing the filament and the experimental procedure are described in the paper and it is suggested that the method which is not in general use, may be capable of much wider application in chemical investigation The results also show that adsorbed oxygen films on tungsten surfaces are held by enormous binding forces, very much greater than those corresponding to the heat of dissociation of the oxygen molecule The method makes use of the fact previously discovered by Langmuir and Kingdon that a minute trace of cæsium vapour may produce an electron emission from heated tungsten up to 640° abs many billion fold greater than that from pure tungsten At higher temperatures this emission passes through a maximum at 715° abs and decreases with further rise in temperature This drop in emission is due to the evaporation of the cæsium from the surface The oxygen increases the stability of the cæsium film, holding it much more firmly than tungsten does, and the effect of the presence of an oxygen film is to hold cæsium atoms which would otherwise evaporate under the same conditions of temperature and pressure

Grassland Research in the British Empire.

THROUGHOUT the British Empire there are vast tracts of natural pastures which produce herbage of an inferior nutritive value A large body of evidence has been accumulated in recent years to show that this low nutritive value is to be correlated with deficiencies of inorganic constituents, such as calcium, phosphorus, and chlorine, in the herbage, a condition which is the outcome of growth on mineral deficient soils Animals ranging over these pastoral areas and subsisting exclusively on such mineral deficient herbage, display a low rate of growth and production compared with what is possible on good cultivated pastures With this decreased growth rate are usually associated lowered fertility and susceptibility to various forms of disease

During 1926, the committee appointed by the Economic Advisory Council to consider the question of the mineral content of natural pastures recommended that practical investigations should be carried out in a suitable colony or dependency with the view of ascertaining whether the nature of such deficiencies could be determined and the diseases due to them prevented Following this recommendation, a scheme of research was inaugurated which serves as a model of successful co operative effort Kenya Colony was selected as the site of the investigations, and Dr J B Orr, director of the Rowett Research Institute, Aberdeen, assumed the general scientific direction The Empire Marketing Board rendered signal help by placing generous funds at his disposal Close and enthusiastic co operation was established between his own staff of research assistants, some of whom worked in Aberdeen and others in Kenya, and the staff of the Agricultural Department in Kenya Colony In addition valuable assistance was given by settlers in the colony, many of whom provided animals and facilities for feeding experiments

The initial outcome of these important investigations is revealed in the Report now before us which has been drawn up by Dr Orr in association with Mr A Holm, director of agriculture, Kenya * Though the main scheme of work is still in its early stages, the results so far obtained are of the highest economic significance and amply justify the trouble which has been taken to secure them

It has been shown that the most striking deficiency in the natural pastures of Kenya is that of phosphorus Indeed, in one district, Molo, the deficiency of this element is as great as that found in certain areas of South Africa, where it is the cause of disease in cattle On the other hand, in another district, Naivasha, the pasturage, apart from deficiency in sodium and chlorine, is as rich as the herbage of good British cultivated pastures The application of different fertilisers in the most deficient area increased the yield of herbage from 25 per cent, where common salt only was used, to as much as 400 per cent where nitrogenous and phosphatic fertilisers were employed The provision of small amounts of the deficient minerals to animals grazing these areas was followed by an increase of 30 per cent in the yield of dairy cows, 10 per cent in the rate of growth of lambs, and about 10 per cent in the weight of the fleeces of sheep

It was discovered that 'Nakuruitis', a local disease resembling the 'bush sickness' of New Zealand, could be prevented by allowing animals access to a mixture of common salt and iron oxide This method of prevention is now being applied with successful results on several farms in Kenya, oxen being kept in good condition for at least a year, whereas formerly, without the use of this simple salt lick, it was impossible to keep them free from the disease for longer than six months without sending them away for a period of grazing in another district

Medicinal Cod Liver Oil *

ALTHOUGH the medicinal value of cod liver oil has been known for 150 years, it is only recently that it has been attributed to the presence of vitamins A and D It is now known, moreover, that different samples of oil vary widely in their vitamin potency as well as in their more obvious chemical and physical characteristics The principles underlying the production of a fine medicinal oil of high activity should be established so that consumers can always be certain of obtaining full benefit from its administration The recently issued Empire Marketing Board Report by Profs J C Drummond and T P Hilditch provides specifications for cod liver oil which are based on the examination of a large number of samples over several years, and makes recommendations for suitable methods of manufacture

The investigators examined oils from Newfoundland Scotland and the North Sea, Iceland, and Norway, obtained at different seasons, for vitamin potency, colour and fatty acid content, and estimated their saponification and iodine values oils from other fish were also compared with cod liver oil Vitamin A was estimated both by the growth test on rats and by the antimony trichloride colour test in a series of oils very fair agreement between the two methods was obtained, so that the quicker and simpler colour test was used during the greater part of the research as an estimate of the vitamin A potency Using standard conditions, the results can be expressed in Lovibond blue units, it was not found possible to express the results of assays by the biological method in units, owing to the errors of the animal test Vitamin D was estimated by the degree of deposition of calcium at the ends of the long bones of rachitic rats as observed under X rays and following staining with silver nitrate (the 'line test') the assays were carried out against the standard preparation of irradiated ergosterol employed by the Pharmaceutical Society and the results expressed in terms of the Coward antirachitic unit

The Newfoundland and Icelandic oils had the highest vitamin potency, the Norwegian the lowest, with the Scottish intermediate, but usually of the same order of activity as the latter The vitamin A and vitamin D potencies were usually parallel

A detailed chemical examination of the constituent fatty acids of cod liver and other oils was made the methods and results have been published in full in the *Biochemical Journal*, by Guha, Hilditch, and Lovern (vol 24, p 266, 1930) and by Lovern (*ibid*, p 866) The general composition of the fatty acids of cod liver oil is stearic and myristoleic acids, traces only, myristic acid, 3-7 per cent, palmitic acid,

* The Relative Values of Cod Liver Oils from Various Sources By Prof J C Drummond and Prof T P Hilditch (E M B 35) Pp 129 (London H M Stationery Office 1930) 1s net

7·13 per cent, palmitoleic acid, 13·20 per cent, oleic and linoleic acids, 18·33 per cent, unsaturated acids containing 20 carbon atoms, 19 32 per cent; unsaturated acids containing 22 carbon atoms, 10·19 per cent The depth of the yellow colour of the oil was found to be roughly proportional to its vitamin potency

The variations in potency of different samples are not apparently directly dependent on the age or sexual condition of the fish, but on the character and amount of the food eaten, which varies according to the season On the other hand, examination of the fish and several crustacea which form the food supply of the cod showed them to be singularly devoid of both vitamins It has been shown that phytoplankton synthesise vitamin A (Ahmad, *Biochem Jour*, vol 24, p 860, 1930) zooplankton contain none and neither contain appreciable quantities of vitamin D, although there may be small amounts present in zooplankton There is no evidence that the cod can synthesise either, though the possibility cannot be excluded The alternative is that the fish retains the small amounts in its food in its liver, so that over a course of months with a plentiful food supply this organ comes to contain considerable amounts The potency of the oil varies inversely with the amount obtained from the liver prior to spawning there is a utilisation of the liver fat, especially in the female, but the vitamin store is not proportionally depleted, so that the oil has a high potency The authors believe this to be the explanation of the high vitamin content of Newfoundland oil

From an examination of the effects of different methods of manufacture upon the palatability, keeping properties, and potency of the oil, the following procedure is recommended Livers should be fresh and steamed immediately they have been removed from the fish Steam at 60 100 lb pressure per sq in gives better results than steam at a lower pressure, and the process should not be too short Subsequent refining should be restricted to removal of moisture, debris, and stearine by chilling and centrifuging or pressure, finally, medicinal oils should be stored in vessels impermeable to light and containing as little free air space as possible Deterioration is caused by the activity of the liver enzymes, hence the necessity for using only fresh material and for adequate steaming to destroy them High pressure steam also gives a higher yield of oil It was found that the replacement of air in the storage casks by an inert gas was difficult to carry out properly and did not increase the keeping properties of the oil Protection from light and undue exposure to air is, however, of great importance

As a result of their work, the authors put forward the following specifications for medicinal cod liver oil The colour, when measured in a 1 in cell, should not be greater than 10 yellow Lovibond units and 0 5 red unit The free fatty acid (as oleic acid) should not be greater than 0 5 per cent, preferably below 0 3 per cent The unsaponifiable matter should not be more than 1 5 per cent, preferably below 1 per cent The vitamin A colour test should give a higher value than 7 blue Lovibond units, when carried out by the authors' technique For oil intended for farm stock, the colour and free acidity may be slightly greater but the amount of unsaponifiable matter and vitamin A present should be the same There appears to be no doubt that oils from Scotland and, especially, Newfoundland are capable of meeting those specifications

Mosquito Control *

THE Report for 1930 of the British Mosquito Control Institute, Hayling Island, Hampshire, is a record of two and a half years' work, the previous Report having been presented in June 1928 The Institute, it may be added, was built and equipped in 1925 by Mr John F Marshall, who has since occupied the position as director without remuneration It was incorporated by licence of the Board of Trade in February 1927 and, by a deed executed at the same time, the building and its equipment were leased to trustees for a term of years No financial aid is received from any official funds, and the income of the Institute is derived solely from the results of its own activities and from subscriptions and donations Funds are greatly needed in order to enable the work to become more self supporting, since the present income falls a long way short of covering expenditure

The activities of the Institute have markedly increased since the issue of the last Report, and the interest shown by the outside public in this work is borne out by the fact that more than 1400 visitors (scientific and others) inspected the museum and laboratory during 1930 Advisory work relating to mosquitoes, their identification and control, is carried out by means of inspection and by correspondence Inspections are generally undertaken by the director's assistant at a pre-arranged charge which includes the submission of a report and the recommendation of remedial measures Various lines of investigation have been carried out during the period under review, including tests of fly killing preparations and of cresol-containing larvicides, at the request of commercial firms A study has also been commenced with regard to the breeding of arboreal mosquitoes in cavities (natural and artificial) in sawn off parts of trees of different species

In June 1929 a special malaria course, arranged in connexion with the League of Nations and the London School of Tropical Medicine, included in its programme a three day visit to the Institute for laboratory and field instruction A number of medical officers took part in this work. In September 1930 a week's course, of a tentative character, on mosquito research for university students was given, and was sufficiently appreciated to warrant arrangements being made for its repetition during the present year Among other educational activities, the director has delivered lectures on mosquito control to various institutions, etc, while demonstrations have been conducted at a number of scientific meetings, exhibitions, etc By way of technical apparatus, the advances made in connexion with photomicrography and stereograph methods are described in the Report Mention needs also to be made of the small but growing library of the Institute a number of new books have been added both by gift and by purchase, while certain of the more important periodicals are taken in regularly The director of the Institute is to be congratulated upon the initiative and energy he is giving to the development of his charge and on the progress so far achieved

Scientific societies, educational bodies, local authorities, and other associations desirous of supporting this useful work may become 'collective' members Members (whether individual or collective) subscribe one guinea per annum and receive a copy of the publications of the Institute

Grey and Red Squirrels in Britain

FOR years, naturalists have been familiar in a general way with the aptitude shown by the American grey squirrel for colonising parts of Britain, with the controversy regarding the harmfulness or otherwise of its habits, and the allegation that it has driven the native red squirrel before it. Never before, however, has an attempt at all comparable with that of Mr. A. D. Middleton * been made to collect all the facts regarding this undesirable alien before passing judgment upon it. The paper also contains information relating to the fluctuations and decline of the red squirrel in Great Britain, so important that this species, too, might well have shared a place in the title.

So long ago as 1830, the grey squirrel was known in Montgomeryshire and Denbighshire, but the present state of affairs is almost wholly due to introductions since 1890. Thirty-three different introductions, involving twenty-nine localities, have been traced, and the sum of their results is astonishing. By 1930 the grey squirrel, according to Mr. Middleton's thorough census, had populated a total area of approximately 13,350 square miles, mainly in southern England, Cheshire, and Yorkshire, and there is every reason to believe that it will eventually cover the whole country, with the possible exception of mountainous districts such as northern Scotland.

Although much of the evidence regarding the food of the creature is unbalanced or biased, there can be little doubt that it is a nuisance in Great Britain. Green food, fruit, and nuts form the major part of the food supply; but it robs birds' nests of their eggs and young, and the damage it does to woodland by biting off young shoots and leaders, and by peeling or ringing the bark of young trees (the present writer has seen branches of old trees girdled as well), is enough to condemn it in the eyes of every forester. The fact that at least 750,000 acres of new forest are in progress of being planted suggests that here lies a potential food store to encourage fresh colonisation, and points to a new danger in the presence of the grey squirrel.

It has often been said that the grey squirrel kills out or drives away the native red squirrel, but no direct evidence of such antagonism has been forthcoming. The present writer agrees entirely with Mr. Middleton's view that in many areas (in Scotland, at any rate) the red squirrel has declined, apart altogether from the presence of its possible rival. Nevertheless the red squirrel almost holds its own in some of the extensive northern forests, and it must surprise many readers to learn that the Highland Squirrel Club, in a limited area confined to thirty-six estates in the north of Scotland, destroyed in the years from 1903 to 1929, 82,000 squirrels.

In considering the future possibilities of the introduced grey squirrel as a serious economic pest, it is well to remember that, so far as Scotland is concerned, the red squirrel itself is a species that was reintroduced after it had almost or wholly disappeared, about the beginning of the nineteenth century. One would imagine that the tale of the risk of introductions was written plain enough for anyone to see, and yet the process goes merrily on: within the last few years the musk rat has been added to the Scottish list of aliens likely to call down future curses upon the heads of its thoughtless or ignorant sponsors.

Birthdays and Research Centres.

April 2, 1853.—Prof. P. PHILLIPS BEDSON, emeritus professor of chemistry, Armstrong College, Newcastle-on-Tyne.

In describing some experiments on the gases enclosed in certain varieties of coal dust, at a meeting of the North of England Institute of Mining and Mechanical Engineers in 1888, I directed attention to the fact that the inflammable constituent appeared to contain other members of the paraffin series in addition to methane (marsh gas). In the discussion, the late Sir Charles Parsons suggested that the examination of the gases released from the coal yielding such dust, by grinding it in a vacuum, might afford information on the composition of these gases. In the session 1913-14, I had contrived a method of testing this suggestion, but was unable to complete the investigation, as on the outbreak of War the buildings of Armstrong College were taken over by the military authorities, and when possession was regained in 1919 opportunity for pursuing the investigations further did not present itself. In 1921, I resigned from the professorship of chemistry in Armstrong College and came to reside in the south of England. The repetition of this work in the light of the influence of these gases on the ignitability of mixtures of air and coal dust, and the examination of firedamp for the presence of other paraffin hydrocarbons than methane, is a problem to which attention might usefully be given.

April 5, 1865.—Sir JOHN BRETLAND FARMER, F.R.S., emeritus professor of botany and formerly director of biological laboratories, Imperial College of Science and Technology, London.

Amongst the various lines of research in which I happen to have been specially interested, there are few, I think, which offer more attractive possibilities than those which concern excretion, in the larger sense of the term. The mechanism by which sugar in a concentrated state is excreted in nectaries (and by various other non-floral glands), though doubtless not too easy to investigate, is one which can surely yield a much larger harvest on the way towards its solution than it has yet produced. Of course, it may be said that the whole matter is a question of energy—and this observation was actually made to me by a very eminent physiologist of his day, some twenty years ago. But it is clear that very little is thereby really gained. No doubt the energy for moving a train is derived from the combustion of coal in the engine, but that tells nothing of the *machinery* and of the steps whereby the energy derived from oxidation of coal is enabled to be utilised for moving the train.

A set of problems akin—perhaps more than is at first sight obvious—to those just referred to, concern the internal movement of water within the higher plant, wherever protoplasm takes a hand in the matter. Much has from time to time been written about 'root pressure', but how much is really *known* as to the *Wesen* of root pressure? It is a subject I have myself pursued, not too successfully, for a number of years, though I did find a few side tracks which seemed to be more hopeful than the main route. It would be useful to know to what extent and under what precise conditions the sugars derived from the surrounding living parenchymatous cells find their way into the dead wood vessels. Semi-permeability has really ceased to be a rigorous dogma where living protoplasm is concerned. It is another example of the truth that 'circumstances alter

cases' By that same track we get into closer touch with the problems of spring bleeding so characteristic of many trees, etc, though in different degrees, and varying under different external conditions

In concluding the few remarks, which have filled more than the space allotted to me, may I venture to suggest that many of our younger botanists, particularly those who are physiologically minded, might profitably acquire a larger horticultural knowledge of growing plants than most of them seem to possess? The problems of the garden are numerous and profitable, but a practical fore knowledge of the garden and its denizens is essential for their recognition, the garden is a more fertile source of inspiration and research than many shelves of 'pickle' bottles

April 5, 1868—R H Burne, F R S, physiological curator at the Royal College of Surgeons, London

During the past few years I have been much interested in certain peculiarities of the lymphatic system of Teleostean fishes, which suggest that in the early stages of its differentiation the lymphatic system comprised both afferent and efferent factors comparable to arteries and veins I am now carrying on similar researches into the constitution of the pseudo lymph system in the skin of Elasmobranchs, in the hope of determining the nature of the 'cutaneous veins' and their morphological relationship to the rest of the vascular system and to the cutaneous lymphatics of other fishes

April 11, 1890—Prof E K Rideal, F R S, professor of colloid physics in the University of Cambridge

We are engaged in determining the potential difference existing at air liquid interfaces and also at gas metal interfaces This potential difference is modified to a marked extent by the presence of a unimolecular film, for example, a fatty acid film on a water surface or alcohol on a gold surface These changes caused by films of different types, of different surface concentrations, of films undergoing chemical reaction or simple solution or evaporation, can be measured with considerable accuracy

Societies and Academies

London

Institute of Metals (Annual General Meeting) Mar 12—**C E Pearson** and **J A Smythe** The influence of pressure and temperature on the extrusion of metals The paper describes experiments made in a small press on the extrusion phenomena of the metals lead, cadmium, bismuth, and tin The chief part of the work is concerned with the determination, under precise control, of the relationship between the rate of extrusion, pressure, and temperature This relationship is expressed in a series of curves, the mathematical treatment of which is indicated—**J D Grogan** and **D Clayton** Dimensional stability of heat-treated aluminium alloys Careful search has failed to reveal the occurrence of secular change in certain commercial heat-treated aluminium alloys, subsequent to the completion of the normal ageing process Serious dimensional changes occur when machining operations are carried out on material quenched in cold water—**D Hanson** and **M A Wheeler** The deformation of metals under prolonged loading (1) The flow and fracture of aluminium The principal method used consisted in examining the changes in microstructure of polished specimens, subjected to static stresses at room and elevated temperatures The extension under a prolonged load that will ultimately break the metal may be considered as consisting of a period of primary extension, during which the rate of flow diminishes, a period during which flow is very slow or even suspended, and a period during which the extension again increases continuously until fracture occurs Failure under creep conditions may be due to intercrystalline cracking, resumption of slipping within the original crystals, or recrystallisation Failure of aluminium under various conditions was examined Rupture of the crystals probably commences along slip planes formed at an early stage in the deformation of the metal—**K L Meissner** The effect of artificial ageing upon the resistance of super duralumin to corrosion by sea water A different 'pock form corrosion', combined with highly deleterious effect on the tensile properties, and primarily caused by intercrystalline corrosion, was found in an intermediate range of annealing temperature at 125° 145° C, and especially at 140° C—**S L Archbutt** and **W E Prytherch** Investigation of the effects of impurities on copper (7) The effect of antimony on copper—(8) The combined effect of antimony and arsenic on copper In the antimony copper series, alloys containing up to 0 85 per cent antimony have been studied, and in the arsenic-antimony copper series, up to 0 5 per cent of each impurity together In the former series, alloys containing up to 0 47 per cent antimony withstood hot rolling and up to 0 85 per cent cold rolling from cast billets An alloy containing 0 85 per cent antimony was hot short In the latter series all compositions withstood rolling either hot or cold Antimony is highly soluble in solid copper, and small additions of this element to copper low in oxygen are found to improve the tensile strength at ordinary temperatures and at 250° C the fatigue properties, and to raise the softening temperature (of cold worked material), without impairing ductility or toughness Copper low in oxygen, containing antimony and arsenic together, appears to withstand hot rolling better than with antimony alone The mechanical properties of copper low in oxygen are improved by small additions of antimony and arsenic together Both impurities lower the electrical conductivity of copper **L J Brice** Some properties of silicon-'aluminium bronzes' The paper describes the results of a detailed study of the Brinell hardness, mechanical properties, and microstructure of three typical aluminium copper alloys, containing respectively 5 0, 7 25, and 10 0 per cent aluminium, with the addition to each of up to 5 0 per cent silicon—**Owen W Ellis** The rolling of alloys of copper and phosphorus containing up to 5 per cent of phosphorus The plain phosphorus copper alloys can all be successfully hot rolled at 450° 650° C to produce strip 0 021 in thick, provided that only small reductions of thickness are made at each stage of the rolling In this way the copper copper phosphide eutectic structure is thoroughly broken up, and the strip can then be cold rolled to 0 015 in

Paris

Academy of Sciences, Feb 16—**Jean Rey** The conditions for the best utilisation of the energy of warm water, natural and industrial—**Georges Claude** Remarks on the preceding communication—**E Mathias** The destructive effects of lightning upon plants A discussion of the cause of the observed fact that when a single tree is struck by lightning and killed, and the lesions on the tree are obvious, plants and trees within a certain radius of this tree also die, although there are no lesions to account for this—**Edmond Sergent, A Donatien, L Parrot**, and **F Lestoquard** Etiological considerations on north

African bovine theilerosis Nine tenths of the cases occur between June 15 and Aug 31 in each year This is explained by a study of the life histories of the micro organism *Theileria dispar* and the transmitting tic, *Hyalomma mauritanicum* —Paul Pelseneer was elected *correspondant* for the Section of Anatomy and Zoology, in succession to the late A Brachet —**Potonniée** The discovery in Russia of unpublished letters of Nicéphore Niepce, the inventor of photography —**J Doubnoff** The fundamental tensors of a rectilinear congruence —**Mlle Marie Charpentier** The Peano points of the equations $y' = f$ for which the unicity of the solution is assured of one side —**Georges Bouligand** The commencing movement of a liquid mass —**Benjamin Jekhowsky** Exact and simple formula for the identification of the minor planets —**J Dourgnon** and **P Waguet** The photometric properties of rough diffusing surfaces —**R Zouckermann** High frequency discharges in nitrogen in the presence of mercury —**G A Boutry** The characteristic surface $i = f(F\ V)$ of a photoelectric cell with a gaseous atmosphere —**E L Harrington** The nature of the radioactive groupings of atoms Although it is probable that groupings round impurities as nuclei may take place, it is doubtful whether the presence of impurities is the essential factor The nucleus may be a particle of an impurity, but is generally a stable association of ionised radio active atoms —**Mme Mathieu, Mathieu, and Paic** Some reactions produced in the solid state A list of chemical reactions between two solid substances is given It is suggested that reactions produced by grinding in a mortar would be those in which the molecular volume of the system would be reduced by a reaction, but this does not appear to be the case, with the examples given —**H Muraour** and **G Aunis** The laws of combustion of colloidal powders (explosives) containing vaseline —**E Rinck** An allotropic transformation of calcium in the solid state Experiments are described, proving the existence of two allotropic varieties of the metal calcium, the transformation point being 450° C —**E Carrière** and **Raulet** Contribution to the study of the sodium silver hyposulphite complexes —**L Hackspill** and **J Weiss** The hypophosphites of cæsium and of rubidium The properties of cæsium and rubidium hypophosphites resemble those of the other alkaline hypophosphites Their density increases in the same sense as their atomic weight, and the decomposition on heating is similar to that of the other alkaline salts —**Mme Ramart-Lucas** and **Mme Bruzau** Absorption and reactivity of the ketone function Arguments against the theory of steric hindrance, with special reference to the case of the hexalkyl acetones It appears possible to explain the variations in the chemical activity of the ketonic group by a mutual influence between the alkyl radicals present in the molecule without steric hindrance intervening —**A Mailhe** and **Renaudie** The transformation of the butylenes into liquid hydrocarbons Study of the catalytic action of silica at 650° 700° C on the butylenes —**Léon Moret** Discovery of the Purbeckian in the Semnoz Chain, near Annecy (Haute Savoie) —**V Perebaskine** Observations on the geology of the Gabon —**Roger Heim** The spore in the genus *Inocybe* —**St Jonesco** The formation of anthocyanic pigments in the etiolated shoots of buck wheat and of wheat —**E Michel-Durand** The influence of light on the migration of nutritive material at the moment of bursting of buds —**A Brunel** The presence of allantoinase in many fungi The ferment is recognised by its converting allantoin into allantoic acid a list of 66 fungi containing allantoinase is given —**Mme L Randoin** and **R Lecoq** Constitution of a new food regime for the study of B avitaminoses, containing reduced proportions of glucides but rich in lipides —**A** and **R Sartory** and **J Meyer** Phenomena resulting from the irradiation of the cutaneous tissue and of the male genital gland of the rabbit as a function of the mode of application of the radiation

Raymond-Hamet The pharmacological influence of the substitution of a methyl group on the β carbon of the methylamino paraoxyphenyl carbinol —**Jean Saidman, Roger Cahen, and Jacques Forestier** The action of electric fields of very high frequency on organic tissues Description of the technique found best for human subjects —**J Verge** and **M Vallée** *The treatment of diarrhœa of calves by the bacteriophage* The specific bacteriophage has been isolated from the intestine of convalescent subjects and subjected to further laboratory treatment Accounts of various cases in which the treatment was beneficial are given

ROME

Royal National Academy of the Lincei Communications received during the vacation, 1930 —**U Cisotti** Hemisotropic quintuple tensors —**M La Rosa** and **G Petrucci** A circuit emitting trains of discontinuous waves —**G Mammana** A fundamental theorem of mathematical analysis Treatises on the calculus deal with a theorem of reduction of a multiple series or one of inversion, a theorem of integration and derivation by series a theorem of reduction of total derivative, one of inversion of the order of derivation, etc, as so many detached propositions All these theorems and, in general, all those leading to reduction or inversion of limits are immediate corollaries of a single theorem, and an attempt is now made to establish this with the maximum possible generality —**Maria Nasta** Contribution to the calculation of the critical velocity of motor shafts —**Bice Pelini** Table of the potential of a magnetic lamina with a circular rim A description is given of the method of compiling a table to show, for various points in space and with an error less than 1 in 1000, the potential of a magnetic lamina with a circular rim and with unit intensity of magnetisation —**G Krall** Problems of the dynamics of the binary —**E Segrè** The Raman effect of acetylene An apparatus for the study of the Raman effect in gases in the visible spectrum is described, and the results obtained with acetylene are given —**D Graffi** Considerations on the theory of the transmission of heat by forced convection —**A Baroni** Methylselenomercaptan This compound, CH_3SeH, obtained by treating an alcoholic solution of sodium hydroselenide with methyl iodide, is an almost colourless liquid of persistent, unpleasant odour and boils at 12° C The mercury, lead, silver, copper, and bismuth derivatives are described —**Giovanni Sani** Investigations on oleastene, a hydrocarbon contained in the fruit of the olive The formula of this hydrocarbon is at least C_7H_{12} and is probably $C_{21}H_{36}$ —**G Mezzadroli** and **E Vareton** Action of ultra short magnetic waves (λ2 3 metres) on silk worms The best procedure to be followed, in applying these waves to silk-worms, is described The weight of the cocoons formed by the irradiated worms is greater by 19 per cent than that of the cocoons from the controls —**M Mitolo** The moderating power of the central nervous tissue This tissue is endowed with a moderating power which is of a physico chemical character and is probably due to certain acid-salt systems (phosphoric acid phosphates, carbonic acid carbonates, etc) with an equilibrium near the neutral point and with low dissociation constants, rather than to proteinates —**L. Diary of Societies

MONDAY APRIL 6

INSTITUTE OF CHEMISTRY (Leeds Area Section) (jointly with Society of Chemical Industry Yorkshire Section) (at Leeds) – Dr H J Channon Modern Aspects of Nutrition

TUESDAY, APRIL 7

INSTITUTION OF ELECTRICAL ENGINEERS (North Western Centre) (Annual General Meeting) (at Engineers Club, Manchester) at 7 – J W Rissik and H Rissik Heavy Duty Rectifiers and their Application to Traction Substations

WEDNESDAY, APRIL 8

NORTH EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (Tees Side Branch) (Graduate Section) (at Cleveland Scientific and Technical Institution, Middlesbrough) at 7 –Mr Groves Engineering and Metallurgy

INSTITUTION OF ELECTRICAL ENGINEERS (Hampshire Sub Centre) (at University College Southampton) at 7 30 – I C Grant The Breaking Performance of High Power Switchgear and of a New Form of Quenched Arc Switch

LEICESTER LITERARY AND PHILOSOPHICAL SOCIETY (Chemistry Section) (at Museum, Leicester) at 8 – Annual General Meeting

TELEVISION SOCIETY (at University College).

THURSDAY, APRIL 9

INSTITUTE OF MARINE ENGINEERS (Junior Section) at 7 – E R Chamberlain Developments in Powdered Fuel Burning

INSTITUTE OF METALS (London Section) (Annual General Meeting) (at 83 Pall Mall) at 7 30 —Discussion on The Effects of Re melting and the Use of Scrap

OIL AND COLOUR CHEMISTS ASSOCIATION (at 30 Russell Square W C 1), at 7 30 –W N Bowran Bitumens and their Use in Paints

FRIDAY, APRIL 10

ROYAL ASTRONOMICAL SOCIETY at 5 —L H Thomas A Criticism of Current Theories of Stellar Structure, and a Suggestion —H Roth The Density Distribution in Capella —Dr H Jeffreys On the Cause of Oscillatory Movement in Seismograms —S F Grace Tidal Oscillations in Rotating Rectangular Basins of Uniform Depth —G Shajn On the Behaviour of Certain Simple Multiplets in Stellar Spectra

MALACOLOGICAL SOCIETY OF LONDON (at Linnean Society) at 6

SOCIETY OF CHEMICAL INDUSTRY (Manchester Section) (Annual General Meeting) (at Engineers Club, Manchester), at 7 –Dr A. E Dunstan The Present Position of the Thermal Decomposition of the Lower Hydrocarbons.

OIL AND COLOUR CHEMISTS ASSOCIATION (Manchester Section) (at Milton Hall, Manchester) at 7 —Annual Meeting

SOCIETY OF CHEMICAL INDUSTRY (South Wales Section) (at Technical College Cardiff), at 7 15 —Annual General Meeting

JUNIOR INSTITUTION OF ENGINEERS, at 7 30.—F Russell Difficulties in Power Transmission by Belt and how to overcome them

SATURDAY, APRIL 11

GILBERT WHITE FELLOWSHIP (Annual General Meeting) (at 6 Queen Square, W C 1), at 2 30.—Sir Richard Gregory, Bart. Comets and Shooting Stars (Lecture).

PUBLIC LECTURES.

WEDNESDAY, APRIL 8

ROYAL HORTICULTURAL SOCIETY (at Greycoat Street, S W 1), at 3.30 — Prof E Baur New Scopes and New Methods of Plant Breeding (Masters Memorial Lecture)

THURSDAY, APRIL 9

ROYAL HORTICULTURAL SOCIETY (at Greycoat Street, S W 1), at 3 30.— Prof E Baur The Problem of Evolution (Masters' Memorial Lecture)

SATURDAY, APRIL 11, 1931

Research and Industrial Revival.

AMONG the duties charged on the Advisory Council for Scientific and Industrial Research is that of advising on steps to be taken for the advancement of trade and industry by means of scientific research It was therefore inevitable that in a year of such persistent industrial depression and unemployment, the Advisory Council should be concerned with means by which science could assist in larger measure the restoration of our industries to full health While the diagnosis of our present difficulties lies outside its scope, the latest report of the Advisory Council (Cmd 3789) does not hesitate to assert that the increased use of scientific knowledge and scientific methods by our competitors abroad has been an important factor in the loss of our pre eminent industrial position

No spectacular results characterise this report, and their absence tends rather to emphasise the immense and far reaching contribution which the work of the Department of Scientific and Industrial Research is quietly making in every section of our industrial and national life While, however, there are many industries which have come to realise that our industrial position cannot be recovered unless our natural advantages are exploited to the full and all agencies available are employed for increasing our efficiency, the report affords no warrant for an easy optimism that the importance of research has been generally or even adequately appreciated either in industry or in the State

It is not merely that there are still many firms which are prone to reduce expenditure on research at the first signs of financial stringency and to forget that it is in times of slack trade that research for future developments is of most importance The case of the William Froude National Tank provides a pertinent example of the danger of this attitude As is stated in the report of the Advisory Council, owing to the increasing demands of testing work it had become almost impossible to continue research work in the William Froude Tank constructed at the National Physical Laboratory in 1909–10 through the generosity of Sir Alfred Yarrow The Council accordingly had recommended that a second tank should be erected for research in connexion with ship resistance and propulsion, and for tests on ship forms, propellers, etc , half the cost of which, up to £10,000, should be borne by the Department

While the depressed condition of the shipping and shipbuilding industries may be the cause of the unsatisfactory response to this offer, it cannot

be regarded as an explanation In consequence of the congestion of work in the existing tank, not only was research being hindered, but also orders for testing were accumulating to such an extent that they were frequently withdrawn and sent to the Continent, where in recent years similar facilities have greatly increased It is obvious that if the testing of ship designs is better carried out abroad, orders for construction are likely to follow them abroad By its failure to respond to this offer, the shipping industry clearly was committing suicide, and had not the Advisory Council, in view of the vital importance of this industry to the nation, revised its recommendation and suggested that the whole capital cost of a new tank should be provided initially by the State, the depression in the shipping and shipbuilding industries must inevitably have increased to a point from which any recovery in competition with Continental rivals would have been impossible

The shipping and shipbuilding industries can only be conducted with economy and efficiency if scientific knowledge is applied adequately and at the right time The demand for tests indicates that this is partly realised by the industry, but the rather discreditable episode demonstrates that the scientific outlook does not exercise a decisive influence on the direction of the industry In fact, the industry betrays a tendency to depend upon the State for assistance that should rightly be provided by its own efforts, the debilitating influence of such aid upon individual *moral* has been the most unfortunate result of much otherwise valuable legislation in social reform

Praiseworthy as have been the efforts of the research associations and valuable the results already achieved, the Advisory Council records that here again its chief anxiety is as to the financial stability of these associations This opinion is noted in spite of conclusive demonstration that the greater application of science to industry through such associations is one of the most important factors in industrial recovery While the Advisory Council looks to a time when research associations will be able to dispense altogether with financial assistance from the taxpayer, it is pointed out that the taxpayer benefits directly from such industrial research, which is gradually raising the standard of living

The problem, indeed, is not entirely one of financial support, for some research associations are at the moment actively seeking not so much to achieve further results as to secure the utilisation of those already obtained by the industries they serve To further this, development sections have been organised by a number of research associations, and the Advisory Council recommends that adequate provision should be made for the maintenance and extension of such work It is, of course, the closer contact between the management of research and production inherent in the organisation of research departments by large industrial firms which gives such departments a decided advantage over the research association The latter is essentially designed for the benefit of those firms unable to bear the full cost of such a research organisation and the cost of investigating fundamental principles, and the success of the research association largely depends upon the willingness of the members of the association to co operate in the submission of both information and problems as well as in the utilisation of results

The evidence indicates that a disconcerting lack of appreciation of the fundamental importance of scientific research and even of the value of co operation still pervades important sections of our basic industries Under modern conditions, the idea of trade secrecy still cherished by a few of our industries has lost its value, and trade secrets are never long hidden from the scientific investigator Development now depends on co operation and the prompt application of accurate knowledge, and until these habits of co operation and research have been acquired by such industries, their recovery inevitably lags and the position of the research associations remains precarious

Not the least serious effect of such unstability is that exerted upon the recruitment of the scientific staff It is of the utmost importance to our industrial future that men of proved scientific ability should be recruited and retained for industrial research of this type This cannot be secured if the financial position of the research workers is not reasonably assured, nor indeed can we expect the most efficient work if their minds are disturbed by serious financial uncertainty The Advisory Council strongly urges the support of superannuation under the Federated Superannuation Scheme of the Universities, which allows a man to contribute for the future irrespective of his continued employment at a particular institution

On the more effective organisation of support for research associations generally, the advantages of a compulsory levy are indicated, and the Advisory Council urges the consideration of such methods by the research associations, and

expresses the hope that if statutory authority is necessary, Parliament will place industries in a position to provide the necessary funds when a sufficiently large majority of the firms in any industry express their desire for the imposition of such a levy Before, however, any such levies could be arranged, it would appear that a very much wider education of the industries concerned on the importance of scientific research and its relation to industrial development is required The growth of co-operation appears to be hindered by the same forces which have delayed the much-needed rationalisation and reconstruction of some of our basic industries, and here again their removal is largely dependent on education The report of the Department of Scientific and Industrial Research provides invaluable material for such an educational campaign, and at the present time should be used to the utmost by all who are concerned not merely with the restoration but also with the expansion of our industries

---

Radio Principles and Practice

(1) *Elements of Radio Communication* By Prof John H Morecroft Pp x + 269 (New York John Wiley and Sons, Inc , London Chapman and Hall, Ltd , 1929) 15*s* net

(2) *Radio Telegraphy and Telephony a Complete Textbook for Students of Wireless Communication* By Rudolph L Duncan and Charles E Drew Pp x + 950 (New York John Wiley and Sons, Inc., London Chapman and Hall, Ltd , 1929) 37*s* 6*d* net

(3) *Radio Traffic Manual and Operating Regulations* By Rudolph L Duncan and Charles E Drew Pp ix + 187 (New York John Wiley and Sons, Inc , London Chapman and Hall, Ltd , 1929) 10*s* net

(4) *Radio Data Charts a Series of Abacs providing most of the Essential Data required in Receiver Design* By Dr R T Beatty Pp 82 (London Iliffe and Sons, Ltd , 1930) 4*s* 6*d* net

THE professional worker in radio telegraphy is sorely embarrassed by the natural and simple request so often addressed to him by his non-specialist friends, "Tell me what book on wireless I ought to read, so that I may have an intelligent appreciation of what is happening in and behind my broadcast receiver" He is unable conscientiously to prescribe any single book that will tell the whole story, reasonably fully, in due proportion, and in a language suited to the reader with a general education A general education must not be assumed to include advanced physics, mathematics, electrical engineering, meteorology, solar physics, and the like He may feel that he would like to write such a book it could be done now with some show of authority, of definiteness, and of simplicity , but he has his daily work to do, and so he turns hopefully to each new book list The spate of deplorably inadequate popular expositions which was released by the advent of broadcasting is now happily abated , books, such as these before us, may be expected to contain an informed and balanced survey of the fields indicated in their titles Is one of them the book for his listening friends ? Or for himself ?

(1) Those who know Prof Morecroft's larger volume come to his newer book with a high standard already set This "general review of those parts of the alternating current theory which are of fundamental importance in radio, followed by the specific application of these principles to radio telegraphy and telephony", comes near to being a very good book indeed Its greatest merit is that it is never misleading It omits some things that one would like to see discussed, but the matters selected for discussion are well proportioned, interestingly treated, and quantitatively estimated Its greatest demerit is that the author's familiarity with the concepts of the art leads him to forget at intervals the standard which he assumes for his readers, so that while generally he gives detailed elementary discussions of fundamental phenomena, at times he confronts the student, devoid of "mathematical preparation more advanced than algebra", with unexplained novelties such as uniformly rotating vectors, lagging currents, hysteresis, mutual induction, microvolts per metre, envelopes, and so on Its second fault is that undue compression leads to loss of clarity One feels that a five per cent increase in bulk would give a twenty per cent increase in intelligibility and accuracy For example, the statement that "the number of complete cycles of flow is called the frequency of the current" is inexcusably lax Again, "coefficient of coupling" is introduced as a purely magnetic quantity, without any warning that capacitative couplings are of profound importance in every broadcast receiver

The concluding part of the book describes typical apparatus, and is satisfactorily definite about numerical values Ten pages of 'problems' at the end will be useful to the serious student The book is delightfully produced and pleasing to handle The block-maker might, however, in the next edition allow us to read the graduations on

the footrules set up beside pieces of apparatus to give the scale

(2) The larger work by Messrs Duncan and Drew, more ambitious in title, and apparently wider in scope, is much less satisfactory in execution At the best it reaches a level of pedestrian usefulness to the operator of some specific commercial sets, and at the worst it comes dangerously near sheer nonsense The over all effect is extremely irritating Four pages of instruction on the care of the motor generator do not make amend for this astonishing picture of a magnetic field

"The lines along which the filings are arranged are known as 'lines of force' The lines of force leaving the north pole re-enter the magnet at the south pole, and are considered as having travelled through an infinite amount of space medium from the time they left the north pole until they re enter the south pole The lines of force which issue forth from a weak magnet supposedly extend as far distant as those from a strong magnet, but since, in the latter case, the lines of force are unable to get far away from each other, they are packed very closely together because they occupy the same space medium as the lesser number of lines which issue from the weaker magnet A magnetic field of great density possesses great strength, and the strength of a magnet is dependent upon the closeness of the lines of force rather than the distance they extend"

Nor does the appearance of meticulous care in the prescription of No 100 carborundum and oil for grinding quartz crystals offset the carelessness of the statement, on the same page, that "the oscillations are produced at a very high frequency, proportional to the crystal's thickness"

The physicist will be startled by the statement, "A molecule, however, is composed of *atoms*, millions of them, about which *electrons* are presumed to revolve" The mathematician will be no less startled by "Fig 59—A logarithmic curve", which has a constant slope from the origin to abscissa 5 and zero slope from abscissa 12 onwards Neither will be startled by the statement, " . a temperature of absolute zero This, of course, is an extremely low temperature" .

The only way in which the authors might make a passably good book out of this volume would be to reduce it explicitly to be a book of detailed instruction in the use of named apparatus, and to avoid any attempt to explain principles

(3) The scope of this paper-covered volume is thus defined in the authors' foreword "Government and commercial traffic rules and regulations prescribe the manner in which radio communications shall be handled These operating instructions are embraced in this volume, with other instruction, which should be followed as closely as actual conditions permit A uniform procedure in moving radio messages should be the aim of professional radio operators" It comprises six chapters, dealing respectively with Acquiring the code—Use of "Q" signals Operating rules and regulations of the Radiomarine Corporation of America International Radiotelegraph Convention U S Radio Act of 1927 Ship Act of July 23, 1912 Regulations governing the issuance of radio operators' licences While much of the text is, naturally, concerned with American conditions, the peculiarly international character of wireless communications makes this book of use to wireless operators of other countries

(4) The modesty of price of this valuable work is equalled only by the modesty of its title The avowed purpose of the book is to give the wireless designer a ready means of solving his problems without recourse to complicated formulæ and mathematics But the student who is wise enough to forget that it is a handbook and to take it as a supplementary text book will find that, in working through its thirty nine abacs with the explanatory notes attached to each, he has acquired at once a familiarity with and a respect for the nomogram as a powerful aid to quantitative design in any field, and a sound knowledge of the principles of quantitative design in the field of wireless

The general reader will probably be pleasantly surprised to find how completely the design of wireless receivers has been lifted out of the 'trial and error' state in which it remained for many years The reader who does not require conversion to belief in the abac as a labour-saving device, will yet find food for admiration in the ingenuity which has been exercised to permit the use throughout the book of standard straight-line logarithmic scales, aided where necessary by ungraduated curves to which the ruler or other alignment indicator is made tangent in the setting The publishers might well include, in the new edition which will certainly be called for, a transparent scale on thin celluloid, which is much more convenient for use than the opaque implement suggested by the instruction to use a 'ruler' for alignment

The only faults which have been detected in this carefully arranged work are very minor ones The numbering does not appear to be entirely systematic there is an abac No 18 and a No 18*a*,

No 19 has "stage 1", "stage 2", and "stage 3", represented by separate sheets, while Nos 24*a* to 24*e* have no No 24 associated with them Perhaps more important is the misprint in No 22, where the relative transmission, in the case chosen to illustrate the use of the abac for "Transmission of sidebands by a tuned circuit", is stated to be 0 447 instead of 0 707

The author and his publishers are to be congratulated on the production of a work representing amazingly good value for money

To sum up, the book for the professional worker is certainly Dr Beatty's, and the professional worker's inquiring friend will find it wholesome, if concentrated, meat The friend will find Prof Morecroft always interesting, never misleading, but sometimes incomprehensible, he will find Messrs Duncan and Drew frequently misleading, and too speciously comprehensible to be safe

Science in Literature

H G Wells a Sketch for a Portrait By Geoffrey West Pp 316 (London Gerald Howe, Ltd, 1930) 10*s* 6*d* net

IF the function of a biographer is to produce a living picture of his subject for his own and future generations, he will not have succeeded in his task unless he himself fades completely in word and in spirit from the pages of his biography In providing us with this story of the struggles of a great man, Mr Geoffrey West has done his work well, for as we turn over the pages of this volume and live through the intimate history of Mr H G Wells, the authorship of the work itself drops completely from our ken This is as it should be, and thus an excellent portrait has been produced

Those of us who are now struggling through the lean and hungry forties and can look back on their early youth, twenty or more years ago, inspired as it then was by the glamour of the scientific romances and of the social philosophy of Mr H G Wells, are not likely to forget the debt which they owe him The rising generation of the 1900's, caught between a decaying Victorianism and a rebellious modernism, threw itself with energy into the fight for what it, in its early enthusiasm, called Progress Manhood may mature the judgment, or temper the impatience of youth, but if the altered values of this post-War age in matters of convention and social outlook are at all to be associated with the activities of any group of men, eminent among that band must be the early Wells

The story of the man is no tale of a silver spoon Born and bred in respectable poverty and Victorian gentility, dogged by persistent ill-health, he staggered through many vicissitudes, from inefficient drapery assistant through overworked private school teacher, to the feet of Huxley at South Kensington There early he saw a vision of science in the service of man, and he pursued it relentlessly Material success came to him, but the vision remained a vision

In a sense, one need not produce a biography to reveal the history of a writer A craftsman proceeds straight from experience, and the writings of Wells reflect the structure of the man A pioneer in scientific fiction, he quickly sensed the dramatic element in a field that had not so far been exploited at all, and so he insinuated into the minds of his readers the amazing possibilities of science Throughout thirty years of strenuous writing, there runs this extraordinary thread of continuity in his work—the same theme—that the universal solvent of ignorance is scientific knowledge, scientifically applied this, whether the problem be moral or pedagogic, social or industrial, national or international To the young men who grew up in this hectic period of problem play and problem novel, he was at once a strength and a goad As boys, we passed easily from the schoolboy "Dormitory Flag" stage, to Wells and the "Time Machine", "War of the Worlds", and "When the Sleeper Wakes" A new universe stood revealed before us, a universe of science and imagination, a world of dizzy possibilities It remained only to give direction to this awakened fervour, to set this torch to the ready sense of social and industrial injustice, in order to fire the reformist and inflame the revolutionary spirits of the younger generation "Anticipations", "Mankind in the Making", "A Modern Utopia", "This Misery of Boots", "New Worlds for Old", "First and Last Things", came in hammering succession, and the younger men became violent propagandists, a nuisance to friends and foes alike

As we look back on these easily impressionable years, it is amazing to recognise the uncanny gift of the man He said the things we ached to say His work may date, but it was ripe, just ripe, for its time Wells has never claimed to be more than a journalist, but if so, his journalism was unique

The middle period of Wells is a tale of adolescent struggles, of the scientific exposure of sex, and of a determination to accustom the mind of the reading public to think boldly and openly of the matter, as one would of any scientific problem In this he fought not merely a narrow Victorian convention,

but also a taboo with its roots deep in man's early history In the eyes of those who still have faith in the open discussion and scientific analysis of secret matters, to H G Wells must be given a great measure of credit for a great achievement

Times have changed and we have moved fast since those days, but the indefatigable Wells has effected some amazing revolutions He has multiplied the reading public many fold, he has forced it to read history in fat volumes and to study biology in the nude Beginning his career as an underling in a small private school, he has become the greatest public teacher now living

It is not easy to judge his later activity In an atmosphere of sullen suspicion and industrial chaos, an aftermath of five years of slaughter, he is still idealist enough to pin his faith to international co operation, and yet realist enough to disavow political parties and the League of Nations And now at this stage, still yet in his prime, he projects a work on scientific economics The thread is still unbroken, the vision still beckons him on, but his young men are now mentally middle aged and disillusioned He has outlived them all, but the rising generation is equally disillusioned

H Levy

Movement of Solutes within the Plant

Die Stoffbewegungen in der Pflanze Von Prof Dr Ernst Munch Pp vii + 234 (Jena Gustav Fischer, 1930) 12 gold marks

IN recent years, this subject has again been much in the forefront of discussion, English readers will recall particularly Dixon's onslaught upon the efficiency of the phloem for downward movement of organic solutes, and Curtis's staunch advocacy of the capacity of this tissue to take not only sugars but even nitrates in any direction, as also the series of papers by Mason and Maskell upon the movement of sugar (see Nature, 123, pp 133-135) and nitrogen (see Nature, 126, pp 973-974) in the cotton plant, which supply valuable data which must be taken into account in any future attempt to elucidate the mechanism of movement of solutes in the plant

Unfortunately, Dr Münch, whose monograph on this subject seems in some respects to break new ground, is unaware of these recent papers by Mason and Maskell, but his contribution is interesting and suggestive, in part perhaps because the point of view is rather that of forest botany than purely academic botany, and one main service his monograph performs is to bring again under notice an earlier valuable contribution which was published in a forestry journal

Dr Münch's main thesis is that the system moving water and solutes in the plant may be conceived as consisting of two main components, which may be represented schematically as in Fig 1 On one hand is the lifeless, permeable woody system, full of water, and represented in this scheme by the vessel of water in which the semi-permeable cells A and B are immersed A and B represent semi permeable living cells, connected by a tube with porous, permeable plates at intervals, the sieve tube with sieve plates In the plant, A and B represent living tissues, abutting on the xylem, connected by phloem When A is at a higher osmotic pressure than B, water will be drawn into A and driven out of B, whilst

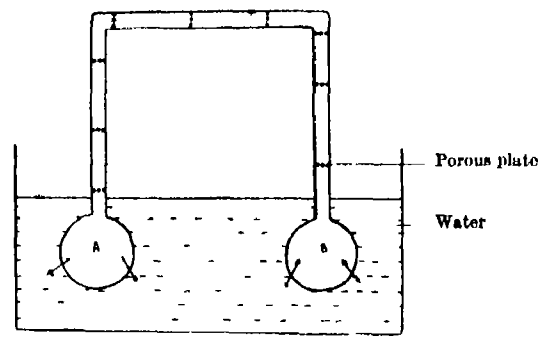

Fig 1

the contents of A will move along the connecting tube into B, so long as the concentration at A remains higher than in B In this manner sap at a higher concentration is drawn along the sieve tubes towards regions of lower concentration, from assimilating leaves, for example, downwards to the growing cambium or upward into a growing fruit

In this connexion, Münch recalls certain earlier experiments of T Hartig and describes interesting observations of his own, which demonstrate that if an incision is made into the phloem of the tree in summer, especially just prior to leaf fall, a definite exudation of sap occurs, sufficient quantities being obtained with patience to permit of some chemical analysis As these drops of sap exude, the pressure in the sieve tube rapidly falls, especially below the cut, so that no more sap exudes from other cuts above and below for a certain distance, which is often much greater below than above These experiments certainly demonstrate the existence of a positive pressure in the contents of the sieve tubes of the current year's growth, but for the system Münch postulates, the flow after

incision seems very slight, and certainly there is little evidence of the vigorous flow through the uncut sieve tubes, as a result of this osmotic, hydraulic mechanism, which the author seems to think is taking place

The sugars moving downwards in the phloem have to reach this tissue from the assimilating cell of the leaf, and Dr Münch tackles anew this great stumbling block in translocation theories How does sugar, so slow in penetrating the normal living cell, manage to move so quickly from the green assimilating cell of the leaf mesophyll into the veins and thus out of the leaf? Dr Münch suggests that the sugar movement may be brought about by different osmotic pressures in adjacent cells, forcing the contents of one cell into the other along the protoplasmic connexions or plasmodesma The sugar in this case is assumed to be in the plasma, not in the vacuole, and to be forced through from cell to cell, moving in the plasma of the plasmodesma strand In the sieve tube, on the other hand, the vacuole is thought to be continuous through the larger pores in the sieve plate, and the sugar is thought of as moving with the water in the manner previously described

These distinctly unusual conceptions of solute movement are accompanied by calculations, based largely upon the assimilation rate of trees, rate of increment of wood, etc, which involve so many assumptions that their value is doubtful, though it is admitted that numerical tests should be applied to our theoretical ideas as to the mechanism of transport at the earliest possible moment But when the increment of wood in the season's growth is used as a basis upon which to calculate the amount of substance that has passed through the inner surface of the cambium by 'exosmosis', the reader may wonder whether the processes of growth and cell division, by which the original framework of these wood cells has been laid down, have not been too completely neglected

Dr Münch has probably done considerable service to botany by directing attention anew to these easily repeatable experiments, which demonstrate that the contents of the young sieve tubes are under pressure, and a pressure which apparently originates from above A re-examination of the possible rôle of the fine plasmodesma strands in the movement of substance in mass is also certainly required, but his monograph will probably not convey to most readers the impression that these problems are solved and the physical mechanism of movement of substances in the phloem now placed beyond doubt

Our Bookshelf

Als Naturforscher in Indien Von Prof Dr Hans Molisch Pp xii + 276 (Jena Gustav Fischer, 1930) 13 gold marks

Prof Molisch's book is a record of a visit to India in the winter of 1928–29 The visit was the outcome of an invitation from Sir Jagadis Bose to the Austrian plant physiologist that he should make his home at the Bose Institute in Calcutta, and that whilst studying the methods and ideals of this establishment, he should give occasional lectures to the workers on matters in his own field, and also carry out any research he desired During the course of the visit, Prof Molisch had full opportunity of seeing India, observing the customs of its peoples, its flora and botanic gardens His various experiences are set down in full, even with intimate detail, the result being rather heterogeneous Nevertheless, the movement, beauty, and sunshine of India continually find their way into the pages of a book generally loosely knit and lacking in construction The photographic illustrations (more than a hundred in number), which deal with all sorts of subjects, are a great feature, they are well selected and well reproduced, largely atoning for the author's lack of literary style Like many travellers, Prof Molisch finds it easier to take good landscapes, crowd pictures, and portrait studies of individuals than to produce good habit pictures of plants

The author deals faithfully with his mission as expounder of the work and inspiring personality of Sir J C Bose, though he does not always accept the precise conclusions that have been drawn Apart from these sketches of the activities of Bose, many chapters are devoted to the vegetation of India, especially from the biologist's point of view There are sections on leaf-fall, the water hyacinth nuisance, mangroves, ants, and numerous physiological and biochemical matters, as well as on botanic and other gardens In a sympathetic account of the Calcutta Botanic Gardens, an appeal for a laboratory, equipped for physiological work, is included Other sections deal with social observances, education, hygiene, and the present day ideals of India Besides a visit to Darjeeling (where Bose has a hill station), attractive accounts are given of some of the principal cities of India and the native State of Jaipur As a whole, the book shows observation, a capacity for being pleased, and a point of view which differs considerably from that of the ordinary tourist

Die Tierwelt der Nord- und Ostsee Begründet von G Grimpe und E Wagler Herausgegeben von G Grimpe Lieferung 17 Teil 2 d_2 *Peridinea*, von Nicolaus Peters, Teil 3 d *Scyphozoa*, von Thilo Krumbach Pp 13-84 + 88 (Leipzig Akademische Verlagsgesellschaft m b H, 1930) 13 50 gold marks

Dr N Peters, who has done much work already on the peridinians or dinoflagellates, gives a good and detailed survey of the group It is well known

that they combine holophytic with holozoic nutrition and therefore are claimed by both botanist and zoologist Some apparently feed exclusively as plants, others as animals, but many feed in both ways The larger naked forms engulf others of their kind, as well as diatoms and other small prey The presence of a large eye with well-developed lens in some of these and nematocysts in *Polykrikos* and others give a special interest to these unarmoured forms Here we find chain formation both in the naked and armoured species, and the beginning of a multicellular state in which individuals are permanently fused and the nuclei are fewer in number than the cells themselves There are many species known from the North Sea and Baltic, but not so many as there are in the Channel, possibly because the region has not been worked so much for these creatures All species are well figured and they are easy to identify We note the absence of *Noctiluca*, which is treated separately in another part of this publication

Dr Krumbach in his account of the Scyphozoa (Part 3 d) shows that of the five orders three are represented here—the Lucernarida with four genera and five species, the Semæostomeæ with four genera and four species, and the Rhizostomeæ with one genus and one species Structure, feeding, and reproduction are fully dealt with, and the author gives a very clear description of the various members of the Scyphozoa, which is well illustrated and up to date

(1) *British Prime Ministers of the Nineteenth Century* By Prof F J C Hearnshaw (Benn's Sixpenny Library) Pp 80 (London Ernest Benn, Ltd , 1930) 6*d*

(2) *Daily Life in Parliament* By H Snell (Routledge Introductions to Modern Knowledge) Pp 74 (London George Routledge and Sons, Ltd , 1930) 6*d* net

(3) *Sinon or The Future of Politics* By E A Mowrer (To day and To morrow Series) Pp 96 (London Kegan Paul and Co , Ltd , 1930) 2*s* 6*d* net

THESE books may suitably receive notice within one paragraph, being respectively concerned with political life of the past, the present, and the future Dr Hearnshaw deals succinctly, but engagingly, with the succession of premiers who guided the Empire's fortunes during a period commencing with Addington and concluding with Lord Salisbury, coincident with the closing of the Victorian era Mr Snell presents a description of the parliament of to day, sufficiently realistic to be welcome Mr Mowrer's contribution is necessarily on less secure ground, as it deals in surmises, based, it is true, upon a logical progression from existing facts and tendencies towards a conceivable future His remarks are cogent and well balanced "We cannot eliminate natural inequality ", " Standardised minds are a relapse of the race into the tribe ", " Under a rational system failure to vote would be penalised " The author's remarks upon Russia and Italy are worthy of close attention Perhaps not unreasonably, he is somewhat pessimistic—" Not for nothing was Sinon reputed the son of that Sisyphus condemned to perpetual stone-(or was it log) rolling ", " What is history but one long series of reforms that have failed ? " For the world as a whole, Mr Mowrer foreshadows internationalism as the over-riding government of to-morrow P L M

Couleurs (étude physique) et colorimétrie Conférence faite au Conservatoire National des Arts et Métiers le 7 mai 1930 Par Prof P Fleury (Conférences d'actualités scientifiques et industrielles, 12) Pp 34 (Paris Hermann et Cie, 1930) 5 francs

IN this lecture, the author points out the difficulties which the accurate specification of colour encounters owing to the physiological nature of the colour sensation He explains how a colour may be specified by the wave-length of its dominant radiation, its luminous flux, and its coefficient of purity, or alternatively by the trichromatic method, which specifies the luminous flux of each of three standard wave lengths, which together produce the colour sensation in question When the sensitivity curves of each of the three sensory elements of the normal eye to light of different wave lengths are known, one method of specification may be converted into the other The author describes the principles on which modern colorimeters are constructed, and states that those based on the trichromatic system are the simplest and suffice for many purposes He believes, however, that for accurate work a combination of a spectrophotometer and a colorimeter on the lines of the instruments of Nutting and of Priest is necessary He hopes that a laboratory for the study of colorimetry will be established in France which will compare with those already at work in the United States, in Great Britain, and in Germany

Simple Geological Structures a Series of Notes and Map Exercises By John I Platt and John Challinor Pp 56 (London Thomas Murby and Co , New York D Van Nostrand Co , 1930) 3*s* 6*d* net

IN this little book, which is of an elementary character, beginners are introduced to the three-dimensional conception of geology, a knowledge of which is essential to progress in the science The maps and sections figured, and the accompanying notes, are simple and straightforward So far as they go, they serve their purpose admirably A more extensive and varied use might, with advantage, have been made of the names of the major divisions of the geological succession In this way the student would, incidentally, be assisted in acquiring familiarity with their correct order of superposition In practice, geological maps are primarily constructed to show age-formational divisions rather than lithological bands

The illustrations represent ideal cases, and users of the book would do well to realise, as indeed the authors suggest in their preface, that in Nature the facts are seldom either so simple or so obvious

Observations of a Low Altitude Aurora and Simultaneous Phenomena.

IN the afternoon of Nov. 16, 1929, during my stay in Abisko in northern Sweden (N. lat. 68° 21′) I observed a rather intensive auroral ray of about 10° apparent length and about ½° apparent breadth in the west-south west *below a completely cloudy sky*. The exact time of the first observation was $16^h\ 18^m$ G.M.T. After about one minute the ray disappeared, but later it appeared and disappeared several times during an interval of about ten minutes. The colour was reddish-yellow. No sound was heard.

The clouds, apparently situated behind the ray, were of stratiform alto cumulus type and consisted of apparently thin and thick strata. The ray began in or in front of a thin stratum, crossed over a thick (more dark) stratum *without appearing less intense here*, and vanished in or in front of the next thin stratum. In the east, similar clouds covered almost completely the sky and *also the full moon*, which was visible only a few times between the clouds. Examining carefully the facts mentioned above in italics, I could not escape the conclusion that the auroral ray must be *below the clouds*, that is, at only a few thousand metres above the ground. On the other hand, it is well known that observations of low altitude auroræ are considered very doubtful and have not yet been confirmed photographically.

A few days later, Mr. Linus Eriksson, at Abisko, told me that he and some other railway employees in Abisko had observed the same auroral display about an hour earlier than I, and also noticed its appearance in front of the clouds. Also, two Norwegian engine drivers on the railway between Abisko and Narvik in Norway had observed the same phenomenon. A report of our observations was sent to Prof. Carl Størmer in Oslo and to the Meteorologisk Hydrografiska Anstalten in Stockholm. In his reply, Prof. Størmer very much regretted that the auroral ray had not been photographed from two places of observation, so that its parallax could have been obtained. A visual observation cannot contribute much more to the most important question if low altitude auroræ really exist than many other similar observations reported earlier. This observation of a low altitude aurora in Abisko on Nov. 16, 1929, has been printed in Swedish and French among my other auroral observations during the period September-December 1929 in "Observations météorologiques à Abisko en 1929", but as I did not wish to increase the number of doubtful observations, it has not been published more exhaustively elsewhere until now.

Reading the most interesting communication of Mr. G. C. Cummings in NATURE of Jan. 17, 1931, p. 108, about a low altitude aurora observed by his brother in Norwood, Ontario, Canada, "early in the winter 1929–30", I inquired the exact time of Mr. Cummings's observation. G. C. Cummings, writing from the Bell Telephone Laboratories in New York, has kindly replied to me in a letter, from which I quote the following lines: "Having received a number of letters from various parts of the world in regard to this Auroral display, it seemed rather important to attempt to establish the exact time of the phenomenon. Accordingly, I communicated with my brother and pointed out the desirability of this proceeding and have just received his reply. As nearly as he can establish it, the time was nine hours thirty minutes in the evening, Nov. 16, 1929, E.S.T. The phenomenon was observed by a number of people, among whom was a telegraph operator who remembered having delivered a certain telegram at the time he observed the Auroral display. Going back through the telegraph files, he located this telegram and was thereby enabled to fix the time within a few minutes. I believe that at least two of the observations reported are almost identical to that witnessed by my brother."

$9^h\ 30^m$ P.M. Nov. 16, E.S.T., is, however, $2^h\ 30^m$ A.M. Nov. 17, G.M.T., so that if Mr. Cummings observed the auroral display in the evening, it was about ten hours later than my observations in Abisko. If, on the other hand, Mr. Cummings's observation was made $9^h\ 30^m$ A.M. on Nov. 16, it was very near the time of the first observations of the auroral display in Abisko. Still, even if the observations have a difference of 10 hours in time, it is very remarkable that low altitude auroræ have been observed on the same day at places so widely distant, and these observations are worth attention and further investigation.

I have therefore also examined the magnetograms of the geophysical observatory at Abisko and my readings of the ionisation in a Kolhörster ionisation chamber,[1] with regard to the time, Nov. 16, 1929. Magnetic disturbance began with a pronounced *impetus* already on Nov. 15, $19^h\ 0^m$ G.M.T., and went on until midnight of Nov. 16. No very great disturbance occurred, however, before $14^h\ 24^m$ G.M.T. on Nov. 16. At this time the vertical intensity gradually decreased and showed a maximum negative disturbance of more than −640 gamma at $15^h\ 16^m$, when the record during a few minutes exceeded the limit of the magnetogram. At $15^h\ 0^m$ the declination made a deviation of 1° 57′ towards east, but turned immediately and made a deviation towards west, which at $15^h\ 16^m$ exceeded the limit of the magnetogram, that is, made an angle towards west larger than 1° 32′. Thus the total oscillation of D during 16 minutes was larger than 3½°. On the other hand, the horizontal intensity did not show any extraordinarily large oscillations. The extraordinarily large deviations in Z and D coincide in time approximately with the first observations of the low altitude aurora of the railway employees in Abisko. At $1^h\ 50^m$ A.M. Nov. 17, G.M.T., a small disturbance occurred, namely −58 gamma in H, 10′ east in D, and +33 gamma in Z.

The following readings of the ionisation were made on Nov. 16, 1929, in Abisko. The values of I, or pairs of ions per c.c. and second, have been corrected for the 'barometer effect' and are valid for the mean air pressure, 720 mm. mercury, whereas those published in Fig. 1 on p. 57 of NATURE of July 12, 1930, were valid for air pressure of 760 mm. mercury.

	G.M.T.	I
Nov. 16	$5^h\ 34^m$ – $7^h\ 4^m$	2·56
,, ,,	7 4 – 9 3	2·68
,, ,,	9 3 – 11 13	2·69
,, ,,	11 13 – 13 23	2·72
,, ,,	13 36 – 17 7	2·83

,, ,,	20 19 – 22 1	2·57
,, ,,	22 1 – 23 46	2·58
,, 17	0 0 – 6 58	2·55

They show a maximum ionisation at the time of the observed auroral display, which is also in accordance with the result found from the observation in Abisko that there is an increase in the ionisation (measured at 388 metres above sea level) during the auroræ and

mentioned in more detail in Lund Observatory Circular No 1, 1931 Usually this increase is only 6 per cent

It is very desirable that the other observations of the low altitude aurora on Nov 16, 1929, mentioned by Mr G C Cummings should be published and that all observations should be compared

Measurement of the Electricity Liberated during the Downgrade Reactions of Organic Compounds

THE liberation of electricity during certain reactions of organic compounds has been well established in previous investigations * In the fermentation of cane sugar by yeast, it was shown that the amount of electricity liberated is proportional to the temperature and concentration of the sugar solution and to the number of active yeast cells, and is only liberated under conditions favourable to the growth of the yeast It was also demonstrated that electricity is liberated during the action of diastase and invertase and during the decomposition of organic matter by bacteria It is suggested that the apparatus employed might be termed a 'fermentation cell'

The following briefly describes a method of measuring this electricity based upon the laws of the electro deposition of metals The apparatus (Fig 1) consisted of a container A (porcelain vessel or wooden box) to hold the research material, in which was embedded a porous pot B containing a solution of copper sulphate, and an electrode C A wire D firmly connected to C terminated in a hook F, from which a copper wire E was suspended in the solution in B In order to localise any deposit of copper, the part of E immersed in the copper sulphate solution except a small area at the lower end, was insulated with shellac To serve as a control, a wire G similar to E, completely insulated except at the lower end, was suspended in B as in Fig 1 For C, carbon rods or rods of corrosion resisting steel, kindly given me by Messrs Hadfield, East Hecla, Sheffield, were used, as these electrodes resisted all chemical action by the research material

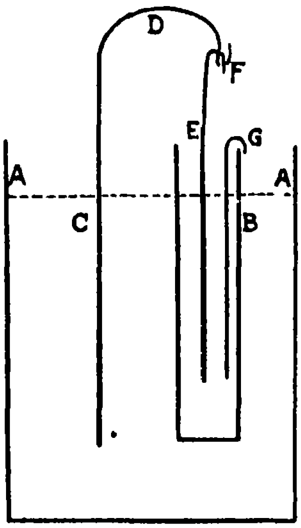

Fig 1

To test the apparatus, a weak solution of hydrochloric acid was placed in A and carbon electrodes used After 24 hours, no copper deposit could be observed upon the ends of either E or G This showed that no electric current had passed through the system When, however, zinc was placed in the solution in A without contact with either B or C, a copper deposit commenced to form upon the end of E, showing that an electric current was passing through the system The copper deposit increased as long as any zinc remained undissolved An experiment similar in all respects, except that the acidulated water in A was replaced by a 15 per cent solution of Barbadoes sugar, was left undisturbed for 48 hours After this period, a slight deposit of copper could be detected upon E with a lens, possibly due to bacterial action On the addition of yeast to the solution in A, fermentation set in and an evident knob of copper gradually formed upon the end of E (Fig 2) It will be allowed that the electro deposition of copper was due to the chemical action of the zinc and acid in the first case, and to that of sugar and yeast in the second

To test whether the copper deposit in the second case could be due to electricity liberated by the reduction of the copper sulphate by the dextrose and levulose in the walls of the porous pot, a fermentation cell was arranged with solutions of sugar of the same concentration in both A and B, and electrodes placed in A and B were connected to two wires dipping into a copper sulphate solution in a separate vessel After the addition of yeast to the solution in A, a copper deposit formed upon the wire connected to the electrode in A The fermentation cell may therefore be regarded as a primary cell, since the electrical effect cannot be attributed to leakage through the walls of B

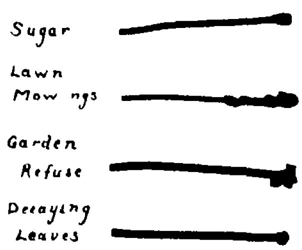

Fig 2

Experiments in which the research material consisted of freshly cut lawn mowings or fallen leaves pressed into a wooden box both showed a copper deposit upon E (Fig 2) As a further experiment, a corrosion resisting steel electrode and a porous pot B containing a solution of copper sulphate were sunk a few inches apart in a heap of garden refuse, the wire E dipping into B being connected with the electrode In this case also, copper was deposited upon E When the porous pot was removed some seven yards from the rubbish heap and the connexions maintained by an insulated wire, copper was again deposited, but much smaller in amount than when the electrode and porous pot were close together Thus it would seem that electricity is liberated in the decay of organic matter in the soil

Experiments show that copper is deposited during the hydrolysis of starch and sugar by weak sulphuric acid

Evidence for the liberation of electricity in the primary cell is given by the galvanometer and the electro deposition of metals Precisely similar evidence is afforded during the decomposition of organic compounds The fermentation of sugar and the decomposition of organic matter take place in a series of downgrade reactions from a higher to a lower potential, and experiments show that electricity is liberated by the enzymic activity of micro organisms during these reactions in a manner homologous to the liberation of electricity in a primary cell

Ordinary explanations to account for these electrical phenomena, such as differences of concentration, production of acid, or a high reducing agent round the electrode, are quite inadequate Any differences of concentration are due to the breaking down of organic matter and the consequent release of energy Moreover, certain of these reactions produce acids, others alkalis, and the heap of garden refuse was distinctly alkaline No further reducing agent is

* Potter, *Proc Roy Soc*, B vol 84 1911 *Proc Roy Soc* A, vol 91 1915 *Zentralbl. f Bakt*, Abt II, Bd 78, 1929 *British Med Jour*, Oct. 29, 1921

required than may be found in the enzymic activity during the hydrolysis of starch and sugar

The weight of copper deposit enables the weak electric currents to be accurately determined

Molecular Spectra of Mercury, Zinc, Cadmium, Magnesium, and Thallium

To obtain a general conception of the energy states of a loosely bound molecule, we have investigated the molecular spectra of mercury, zinc, cadmium, calcium, magnesium, and thallium in emission with an apparatus capable of concentrating excited molecules in a suitable quantity The photometric measurement of the photographic records obtained is summarised in Fig 1, in which the intensity of a continuous spectrum is denoted by a full line, and that of the region with some structure by a dotted line

From the results obtained, it may be generally stated that a 'band system' emitted from diatomic molecules of mercury, cadmium, zinc, and magnesium

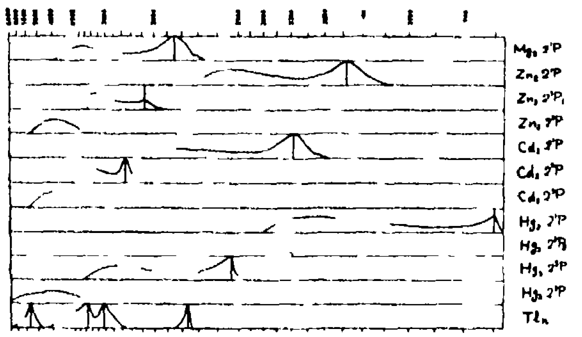

FIG 1

vapours has two broad maxima and one flat minimum of intensity One of these maxima always coincides with the resonance line $1\,^1S_0 - 2\,^1P_1$ or $1\,^1S_0 - 2\,^3P_{0,1,2}$ and the other lies at the region of longer wave length than this resonance line The intensity of the shorter wave length side from the resonance line gradually decreases and terminates rather suddenly at a certain position, while that of the longer wave length side from the second maximum decreases also gradually to a certain point where the band system suddenly breaks off or melts into the continuous spectrum of wide or narrow breadth In the region about this second maximum, there was found a generally coarse structure, the fluted bands occasionally consist of finer bands, while no bands were observed in the region near the resonance line The frequency of convergence of the coarser bands falls somewhere between the frequency of the resonance line and this frequency, plus the energy of dissociation in frequency unit

These experimental results and other details can be explained in the light of recent theoretical considerations put forward by Born Franck, Condon, Winans, and Kuhn, if we assume that the intensity maximum about the resonance line corresponds to that emitted by excited quasi molecules and the maximum on the longer wave length side to that emitted by excited stable (quantised) molecules

The energy of dissociation of a molecule in the normal or the excited states can be calculated approximately, as given in the accompanying table, from the difference of energies corresponding to the frequency of the resonance line and that of the shortest or the longest wave length limit of the band system These values for normal molecules evaluated in this manner are always a little greater than those already obtained by other observers For example, those for the molecules Zn_2, Cd_2, and Hg_2 are 0 29, 0 24, and $\geq$0 07 volt respectively, while Winans calculated them to be 0 25 and 0 20 volt for Zn_2 and Cd_2 from the limits of the absorption spectra, and Franck, Grotrian, and Koernicke as 0 04–0 06 volt for Hg_2 These discrepancies can be explained by taking into account the effect of the kinetic energies of colliding atoms at the temperatures of this experiment

	$1\,^1S_0$	$2\,^3P_0$	$2\,^3P_1$	$2\,^3P_2$	$2\,^1P_1$
Mg_2	0 30				~1 5
Ca_2	>0 18				?
Zn_2	0 29	<1 7	~0 7		<~1 2
Cd_2	0 24	<1 4 >0 9	~0 7		?
Hg_2	$\geq$0 07	<2 8	<1 6 >1 1	~0 2	<1 5

In the case of quasi molecules, the continuous spectrum accompanying forbidden lines $1\,^1S_0 - 2\,^3P_0$ and $1\,^1S_0 - 2\,^3P_2$ is lacking or very weak, while that with the line $1\,^1S_0 - 2\,^3P_1$ is excited, and the greater the intensity the greater is the triplet separation in the atomic spectrum The continuous band due to the transition $1\,^1S_0 - 2\,^1P_1$ is emitted intensely in the case of all the metals From these results, it seems that the intensity rule for the atomic line holds good in the case of the continuous spectrum emitted by quasi molecules, but similar reasoning does not hold good for the stable molecules

Symmetrical and asymmetrical 'bands' accompanying the lines in the spectrum of thallium are probably due to thallium molecules, but nothing could be deduced as to whether the molecule is diatomic or not At any rate, the structure of the band systems at 3776 A and 5350 A differs from that of the diatomic one The continuous branch extending on the shorter wave length side from edges at 3770 7 A or 2766 3 A in the 3776 A band or 2768 A band may be explained as the excess of energy due to the kinetic energies of the colliding atoms

A detailed statement of the investigation will be published elsewhere

Relation between Electrical Resistance and Energy of Magnetisation

IN a recent paper,[1] Gerlach and Schneiderhan have described some experiments on the electrical resistance of nickel as a function of the temperature and as a function of a longitudinal external magnetic field They have shown that in the absence of an external magnetic field there is, in addition to the normal linear change of resistance with temperature, a term which is directly proportional to the energy of spontaneous magnetisation The accuracy with which this relation holds good for all temperatures up to the Curie point is very striking

Gerlach and Schneiderhan have also examined the change of resistance as a function of an external longitudinal field at constant temperature, for a range of temperature around the Curie point The change is shown to be a maximum at the Curie point and to fall off quite rapidly both above and below this temperature Considered as a function of temperature, the change of resistance in a given field varies in a manner strikingly like the variation of the magneto-caloric effect with temperature[2] One is therefore again led to consider this change of resistance as being

a result of the change of magnetic energy which occurs on application of an external magnetic field, since the magneto caloric effect is a direct measure of this energy change There is, however, one difficulty in interpreting these results According to Gerlach and Schneiderhan, the resistance in the neighbourhood of the Curie point varies linearly with the field This result seems to be in contradiction to the rest of the paper for the magnetic energy cannot vary linearly with the field over any protracted temperature range, in fact, in the quasi paramagnetic state above the Curie point, the energy must be proportional to the square of the field In the neighbourhood of the Curie point, the energy may be a complicated function of the 'external' field depending upon the exact relation between the intensity of magnetisation and the field

I have examined the change of resistance near the Curie point for fields up to 7000 gauss, as against the 400 gauss maximum of Gerlach and Schneiderhan Just below the Curie point the resistance is found to vary almost linearly with the applied field, at the Curie point it varies more slowly than the first power of the field, and then with rising temperature the relation changes progressively to a linear relation between the resistance and the square of the applied field This is exactly the course followed by the magneto caloric effect and is therefore in striking agreement with Gerlach's suggestion that the resistance changes linearly with the magnetic energy The transverse effect has also been examined and although differing greatly from the longitudinal effect at room temperatures, it gives identical results both near and above the Curie point This would, of course, be expected if we are concerned only with an energy change

The results of the present work therefore, although differing in one respect from the results of Gerlach and Schneiderhan, confirm the main suggestion made by them concerning the intimate relation between electrical resistance and magnetic energy A more detailed account of the work will be published elsewhere

Effect of Internal Stress on the Magnetic Susceptibility of Metals

IN a very interesting communication in NATURE of Dec 27, 1930, p 990, K Honda and Y Shimizu show that by high pressure the susceptibility of copper is changed * from paramagnetic to diamagnetic The following is a simple explanation of this fact, without any special theory concerning the susceptibility of metals We assume that the high pressure, giving a diminution of density of 0 5 per cent, so far destroys the crystal lattice of the copper that parts of the metal become amorphous, then the susceptibility after the deformation may be considered as due to the diamagnetic portion of the normal lattice together with the paramagnetic parts of the amorphous metal, the latter enclosed as a gas in the crystalline copper It is easy to calculate that, 0 5 per cent of the metal being amorphous, the susceptibility will be changed by the amount given in the communication by Honda and Shimizu At the temperature of re crystallisation, the amorphous parts will disappear and the metal will regain its normal susceptibility—just as observed in the experiments quoted

* Change of diamagnetic susceptibility with stress was found first by H J Seeman and E Vogt, *Ann d Phys*, **2**, p 980, 1929

Scattering of X-Rays by Mercury Vapour

IN a previous note [1] a calculation has been made of the intensity of total scattering of X-rays by monatomic gases according to a formula deduced by A H Compton [2] and C V Raman,[3] and fair agreement is obtained with the experiments of Barrett [4] on the scattering of X rays by helium and argon gases

By a photographic method, Scherer and Staeger [5] have recently studied the total scattering of copper $K\alpha$ radiation by mercury vapour for scattering angles ranging from 20° to 160° It is certainly of interest to compare our theory with these results In particular, as mentioned by Waller and Hartree,[6] there are

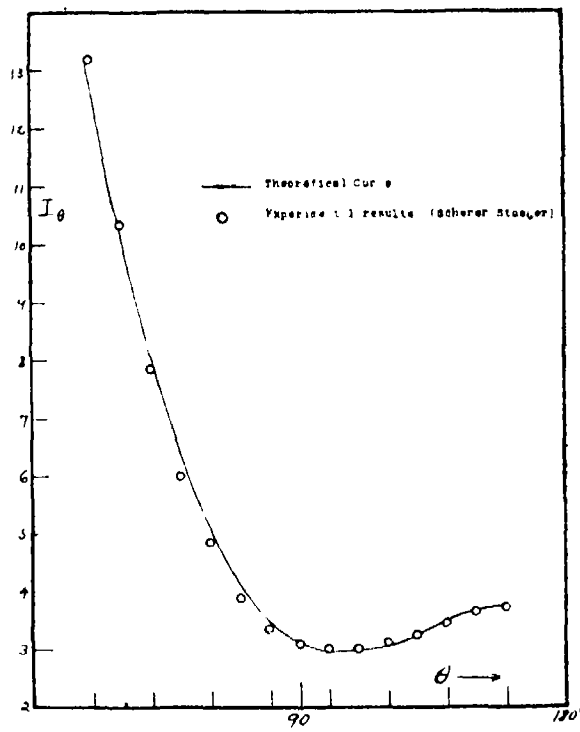

FIG 1

difficulties in applying the wave mechanical theory of X ray scattering recently developed by these authors to the scattering by a heavy atom like mercury, we would like to see how our theory could account for the experiment in this case Such a comparison is made in Fig 1 The full curve represents the theoretical values of the scattering per atom in arbitrary units, plotted against the scattering angle θ The encircled points are the experimental data taken from the scattering curve given by Scherer and Staeger and fitted to the theoretical curve at θ equal to 90° It is seen that the agreement between theory and experiment is satisfactory throughout the range of the scattering angle examined

It may be pointed out that for the scattering of copper $K\alpha$ by mercury vapour, the contribution from the incoherent scattering to the intensity of total scattering amounts to about one per cent Thus the scattering nearly follows the well known expression

$$I_\theta = \frac{Ie^4(1+\cos^2\theta)}{2m^2R^2C^4}F^2,$$

where F is the 'atomic structure factor' (that is, equivalent to ZF of the previous note, loc cit) The

F curve was calculated from the atomic field of Thomas and Fermi as previously employed

Band Spectrum of Bismuth Hydride

A BISMUTH arc, operating in a hydrogen atmosphere at reduced pressure (10–20 mm.), emits the line λ4722 of bismuth (Bi) with great brilliance. A faint band spectrum was found to occupy the vicinity of this line. However, using a quartz discharge vessel, fed with 0.5 amp., 1200 v. d.c., and the bismuth vapour distilling at 900° C. through a narrow end on tube, this band spectrum comes out with great intensity, and so we succeeded in photographing the bands at large dispersion.

The bands are composed of single P and R branches, having their lines well resolved, and consequently we assign the system to a $^1\Sigma - {}^1\Sigma$ transition in the bismuth hydride (BiH) molecule. From an analysis of the bands (0, 0), (1, 1), and (1, 0) the following constants were calculated:

$$\nu_0 = 21278.3 \text{ cm.}^{-1},$$

$$\begin{array}{ll} B_0' = 5.216 \text{ cm.}^{-1}, & B_0'' = 5.066 \text{ cm.}^{-1}, \\ \alpha' = 0.19 \text{ cm.}^{-1}, & \alpha'' = 0.16 \text{ cm.}^{-1}, \\ D_0' = -20.25 \times 10^{-5} \text{ cm.}^{-1}, & D_0'' = -18.5 \times 10^{-5} \text{ cm.}^{-1}, \\ r_0' = 1.791 \times 10^{-8} \text{ cm.}, & r_0'' = 1.818 \times 10^{-8} \text{ cm.}, \\ \omega_0' \sim 1674 \text{ cm.}^{-1}, & \omega_0'' \sim 1677 \text{ cm.}^{-1}, \\ \omega_0'x' \sim 15.5 \text{ cm.}^{-1}, & \omega_0''x'' \sim 21 \text{ cm.}^{-1} \end{array}$$

The vibrational frequencies ω_0' and ω_0'' were derived from the relation $D_0 = 4B_0^3/\omega_0^2$. Up to the very last lines observed ($K = 32$) the rotational structure of the (0, 0) band is well checked by the ordinary formula $F(K) = BK(K+1) + DK^2(K+1)^2$ if we add a small uncoupling term ϵK in the final term ($\epsilon = -0.042$).

The near coincidence of ν_0 with the atomic line λ4722 and the close agreement between the constants of the initial and the final terms of the band system, make us inclined to suggest that the electronic states of the molecule originate from the corresponding states $2s$ and $^2D_{3/2}$ in bismuth, the hydrogen atom remaining unexcited. Our suggestion also harmonises with the appearance of a small, negative l-uncoupling term in the final state of the molecule. Such uncoupling terms are, according to the theory,[1] to be expected in molecular terms derived from atomic P, D terms. It is further of some interest to note that while the triplet band systems known in the spectra of NH and PH are derived from deep lying quartet terms in N and P, the singlet system of bismuth hydride probably originates from the doublet system in bismuth.

A full report of the spectrum will appear later in connexion with the analysis of other band systems of bismuth hydride situated in the red part of the spectrum.

The Values of e, h, e/m, and M_P/m

IN a recent paper,[1] I showed that the six methods usually used for deducing the value of Planck's constant, h, could be used collectively to evaluate both e and h, without assuming any direct determination of e (such as that of Millikan). This seems to be the most accurate way of estimating e and h that is so far available.

I have now repeated the calculations, using all the data referred to by Birge as suitable for estimating h,[2] as well as all the estimates of e/m given by Birge and in the "Handbuch der Physik" of Geiger and Scheel (vol. 22, p. 81). From the values of e and h thus deduced I find

$$hc/2\pi e^2 = 137.01_7 \pm 0.05_9.$$

This is in such good agreement with Eddington's theoretical prediction of exactly 137, that his equation is slightly more firmly established than any of the other equations relating e and h.

By assuming Eddington's equation, the values of e and h can be deduced somewhat more accurately. I give for comparison Birge's estimates:

	Birge	Bond	Difference	Sum of probable Errors
$e \times 10^{10}$	4.770 ± 0.005	$4.779_4 \pm 0.001_1$	0.000_4	0.006_1
$h \times 10^{27}$	6.547 ± 0.008	$6.558_4 \pm 0.003_1$	0.011_4	0.011_1
$(e/m) \times 10^{-7}$	$\begin{Bmatrix} 1.761 \pm 0.001 \\ 1.769 \pm 0.002 \end{Bmatrix}$	$1.769_0 \pm 0.0004_4$		
M_P/m	$\begin{Bmatrix} 1838.20 \pm 1 \\ 1846.61 \pm 2 \end{Bmatrix}$	$1846.6_7 \pm 0.4_4$		

My probable errors should be accurate to about 10 per cent, as the calculations depend on 36 sensibly independent data.

The difference between my estimate of M_P/m and Eddington's theoretical suggestion of $(136)^2/10 = 1849.6$, is 3.0_3, or 6.3 times as large as my probable error. I can only conclude that this is very strong evidence against the value of M_P/m being exactly $(136)^2/10$.

I write this in memory of J. R. B.

A New Band System of Copper Hydride

A BAND system consisting of six band heads has been found in the region λλ2900–2200. It is different in nature from the two systems previously known for the molecule. The bands are double headed, indicating that their emitter consists of an odd number of electrons, and thus they have been attributed to the ionised copper hydride (CuH^+) molecule. The band structure has been analysed. It consists of nine branches, namely, six main branches and three satellites, and the branch lines obey the K selection rule. From the intensity relations of the branch lines for low quantum values, it is found that $Q > R > P$. Thus the system has been assigned a $^2\Pi \rightarrow {}^2\Sigma$ transition. The $^2\Pi$ level is inverted. From the vibrational quantum analysis, $\omega_0'' = 1874$ cm.$^{-1}$. This is in good agreement with the value as calculated from the relation given by Kratzer, namely, $\omega_0^2 = -4B_0^3/D_0$. The values of B_0'' and D_0'' are 3.30 cm.$^{-1}$ and -4.16×10^{-5} respectively.

Polarisation of the Raman Spectrum of Water

The Raman spectrum of water has been studied in great detail by a large number of workers, notably A S Ganesan and S Venkateswaran and A L Meyer So far as I am aware, however, no attempt seems to have been made to study the polarisation of the Raman bands I have studied the Raman spectrum of pure water by the original method of Raman The liquid, which was enclosed in a large bulb, had been carefully purified by repeated distillation *in vacuo* The polarisation photographs of the liquid were taken with a fairly wide slit, due corrections in the exposures for the two directions of the nicol, for the polarisation introduced by the optical train in the glass spectrograph itself, having been made by a previous calibration of the instrument

The intensities of the bands were estimated by a plate containing a series of graded exposures of the mercury spectrum The following table indicates the results obtained

Wave number shift (mean) excited by 4358 3 A	Depolarisation factor	Intensity
3100	0 60	Medium
3400	0 48	Strong
3600	0·75	Weak

From these observations I conclude that

(1) The three different Raman bands excited by the same incident lines are differently polarised

(2) The degree of polarisation of the different Raman bands (excited by the same line) seems to increase as the intensity of the band increases

The 3 13μ band has been attributed to a polymer of H_2O But whether the variation of the depolarisation factor is to be attributed to the variation in the geometric character of the oscillations involved, or has a definite bearing on the relative intensities of the bands themselves, is more than we can say at present C Ramaswamy

Thermophilic Bacteria in Milk

Mudge and Thorwaldson [1] have advanced a new theory to account for the proliferation of the so called thermophilic bacteria in milk during pasteurisation at 62 8° C The fluctuations in numbers which occur at short intervals during pasteurisation are so sudden and violent as to require some further explanation than is supplied by mere proliferation, even if it is at its optimum They suggest that the organisms exist in milk as dormant spores which, unless the milk is subjected to the action of certain physical and chemical stimuli such as heat, cold, or the action of alkalis, remain ungerminated

Work which is in the process of completion in this laboratory has furnished evidence in support of this suggestion of Mudge and Thorwaldson, although it was arrived at by an entirely different route During the investigation of a spore forming organism isolated from commercial sterilised milk, it has been found that the germination of the spore, and subsequent spore formation, depends upon the effect of heat

If after inoculation into milk the spores are heated, germination invariably occurs If, however, the culture is not heated, germination is very much reduced and fails in the second generation The original spores are gradually lost by a process of dilution during subsequent cultivation and a stable vegetative form of the organism is obtained

If to a culture of heated spores (possessing the power to germinate) a small quantity of a living culture of the vegetative form be added, a number of these spores are so affected that they immediately lose the power of germination, and if they are allowed to remain in contact with the vegetative culture for 24 hours, this power is lost by all If, however, to a culture of a number of spores, isolated by the Barber single cell technique, which cannot be induced to germinate by heating alone, a small quantity of a *killed* culture of the stable vegetative form of the organism be added, germination, followed by normal spore formation, takes place

It appears that the stable vegetative form, which has been found to dissociate from the sporing form, bears an inhibiting factor which is heat labile It therefore seems that the significance of heating lies in the destruction of this factor, and it may be that the dormancy of the spores of thermophilic bacteria in milk, which is destroyed by heating, is due to the presence of a similar inhibitory factor M I Christian

Two New Colour-types in Cats

During the past year, we have obtained two cats each of which is apparently a new colour type The first seems to be an albino He was exhibited at a cat show in Paris in 1930 and came into our possession shortly afterwards

Hitherto albinism in cats has been unknown White cats do occur and are sometimes referred to as albinos but their eyes are pigmented—often blue, sometimes yellow or green—and the white coat colour is actually dominant white

The white cat in our possession has eyes very like those of an albino rabbit The iris is translucent white, and when the pupil is dilated the eyes look blood red In appearance the cat is a perfect albino but it is not yet known how his colour is transmitted He appeared in a strain of Siamese, and it is of interest to note that the Siamese coloration is the nearest approach to albinism hitherto found amongst cats Siamese in cats is almost certainly comparable to Himalayan in rabbits, and Himalayan is next to the lowest member of the series of allelomorphs extending from black to albino

The second cat is a self brown, very much the colour of ground coffee He was previously owned by the late Mr H C Brooke and was shown by him at the Crystal Palace as a self red Brown coat colour occurs in many domestic animals, but also has not hitherto been recorded in cats Yellow cats are fairly common They are often referred to as orange, red, or marmalade—actually they are yellow with darker, orange brown markings

The self-brown cat in our possession was evidently considered to be such a 'red' without the lighter patches His colour is, however, entirely different from anything found on a red—it is a true dark brown without markings It is not yet known how his colour is transmitted, and nothing is known of his origin

Research in the Modern State *

There are few documents which present a more comprehensive picture of the manifold ways in which scientific research is applied, not only to industrial problems but also to the service of our daily needs, than the annual reports of the Department of Scientific and Industrial Research All the major needs of the population are touched by the activities of the Department—food and clothing, air and water supply, heating and lighting, communications and transport, housing and building—in each of these spheres science is making important contributions, and promoting not material developments alone but also the solution of many problems which menace the national development and health There is no department of State in which the beneficial influence of the Department of Scientific and Industrial Research is not felt, and it is probable that no proportion of the national income is more profitably spent than the comparatively small sum of £711,200 (gross) or £536,746 (net) which represents the expenditure of this Department for the year ending Mar 31, 1930.

The report of the Department for the period, Aug 1, 1929–July 31, 1930, which has recently been published, includes the short report of the Committee of the Privy Council, signed by Lord Parmoor, with the report of the Advisory Council and summaries of the work carried out by the National Physical Laboratory (representing the largest single item of expenditure, £205,301 gross, or £100,418 net), and the Chemical Research Laboratory, by the twenty research associations which are in receipt of grants, and under the direction of the various research boards Appendices deal with the research boards, committees, and establishments of the department, finance, publications, and developments during the period in the organisation of industrial research in other parts of the British Empire The extent to which scientific knowledge is now woven into the fabric of modern life is well indicated by the list of some forty-five research boards and committees and of the twenty research associations, to the support of which grants amounting to £70,931 were contributed during the year The personnel of these committees comprises many of the most distinguished scientific workers in Great Britain, and much of the voluntary service they thus render receives little public recognition As in the year under report, the results of scientific work are seldom spectacular, and even when a fundamental discovery has been made, years may elapse before it becomes a benefit to mankind The absence of spectacular results from the present report, in fact, renders it a more valuable document from which to assess the immense normal contribution such work makes to our common wants

In the course of a short article it is impossible even to catalogue the wide range of subjects coming within the province of the Department, and a few examples only will be selected to illustrate the intimate relationship of its work and our daily life Even to outline the work of the research associations would carry us beyond our limits, and it must be sufficient to refer to the investigations being carried out by the British Non Ferrous Metals Research Association on the effect of frost on the bursting of water pipes, which is to include pipes made of lead, the new lead alloys, copper and iron so far as they are used in domestic installations, and by the Research Association of British Paint, Colour, and Varnish Manufacturers on the durability of films of paint or varnish, etc The tests carried out have already made it possible to obtain much valuable information regarding the probable performance of paint materials in use The British Cotton Industry Research Association has successfully introduced a new antiseptic, 'Shirlan', to protect cloths exported to warm damp climates, and warps stored under damp conditions at home from the deleterious effects of mildew development The British Launderers' Research Association has studied the laundering of rayon, and directs attention to the caution needed in finishing, for example, ironing, such fabrics, whilst the Wool Industries Research Association has reported the unexpected discovery that when sulphur dioxide and alkali are present in particular proportions they assume a phase of exceptional activity By taking advantage of this active range a new, effective, and cheaper process of bleaching has been developed

The increasing use of electricity for domestic purposes is not unaccompanied by dangers Thus, while the necessity for earthing as a means of avoiding the danger of shock or mitigating its effect is generally acknowledged, the means for obtaining a 'satisfactory' earth have not been described, and wide variations exist in practice, some of which are hazardous and others unnecessarily expensive This question, and also the elimination of fatigue failure in the overhead lines now widely used for the transmission of power at high voltages, are occupying the attention of the British Electrical and Allied Industries Research Association By work of this kind, the consumer benefits through obtaining a better article, and in some cases also a cheaper article The standard of living is thus being gradually raised as a result of the application of discovery to production Research on the electric lamp, for example, has enabled the consumer to-day to obtain more than four times the light his grandfather could obtain for the same money

The work of the Fuel Research Board is of outstanding importance, whether for industrial or domestic purposes, and on this work a gross sum of £95,305 was expended Some account of the investigations conducted by the Board has recently

* Department of Scientific and Industrial Research Report for the Year 1929–30 (Cmd 3789) Pp 224 (London H M Stationery Office, 1931) 3s 6d net

appeared in NATURE (Mar 7, p 386), and the results of the study of low temperature carbonisation have led to the formation of a Low Temperature Coal Distillers' Association This work is linked up with the investigation of the tar oils produced as by products which is being carried out by the Chemical Research Laboratory, Teddington The main object of the low temperature carbonisation process—the production of a satisfactory smokeless fuel—can only be achieved if the by-products can find a suitable market, and it is accordingly worthy of note that Bakelite ' and ' Novalak ' resins have been successfully prepared from phenolic fractions of this low temperature tar, whilst interesting results have also been obtained at Teddington in cracking, hydrogenation, and syntheses from the same tar

A closely related problem is that of atmospheric pollution, and the investigations of the research committee dealing with this have now reached an advanced stage Improved methods of obtaining information on atmospheric pollution are being elaborated, including methods for the determination of sulphur in the atmosphere, the approximate total sunlight received, and the lateral distribution of atmospheric impurity from a centre of pollution under different weather conditions

The importance of preventing water pollution was particularly demonstrated during the dry summer of 1929, and has stimulated interest in the work of the Water Pollution Research Board A comprehensive scientific survey of the Tees as a typical river flowing through an industrial centre has been undertaken, and already the general changes in the composition of the river water and in the fauna and flora of the river from source to mouth at different times of the year and under different conditions of rainfall and tide, have been ascertained The very serious pollution occasioned by effluent from beet sugar factories has received special attention, and investigations carried out in co operation with the industry have shown that there are practical methods by which such excessive pollution can be avoided Another investigation in which the Chemical Research Laboratory is also participating is concerned with the difficulties caused by the corrosive action on iron mains and the plumbo solvency of certain waters

The work of the Food Investigation Board entailed a gross expenditure of £38,531, or £14,237 net, with a further £9736 on the extension of the Low Temperature Research Station at Cambridge —figures which seem infinitesimal in regard to the importance to the nation of the successful preservation, storage, and transport of fruit, vegetables, meat, and fish The extension at Cambridge will accelerate the work on meat, in which important scientific and practical results have already been achieved in relation to freezing of gelatin gels and to the factors responsible for loss in ' bloom ' or the freshly killed appearance of lamb Work on the scientific basis of the curing of meat is providing a rational explanation of the customs of the curing industry, which are at present empirical and obscure

The characteristic English breakfast has received special attention, for the programme of work has included large scale investigations on the storage of frozen bacon and on the factors involved in control of the cold storage of eggs During the year, construction of the new station at East Malling has advanced sufficiently to permit research on the storage of fruit on a semi commercial scale, and a report has been published which should facilitate the elimination of wastage in fruit transport and storage, and another on the optimum temperatures and atmospheres for use in the gas storage of fruit, which has led to a remarkably successful method in one of the large commercial stores

Research on the preservation of fish by cold, the smoking of fish, and the bacteriology of fish preservation has been commenced at the Surrey research station This work has been supplemented by work carried out at sea in the steam drifter *City of Edinburgh* and by the Forest Products Research Laboratory, which has undertaken an investigation of the chemistry of wood smoke

Much important work carried out by the Forest Products Research Board is concerned not merely with the development of the forestry resources of the Empire, but also with timber preservation and methods of preventing dry rot or attack by the ' death watch ' beetle or other insect pests Such work like that on the seasoning or creosoting of larch poles to prevent the serious wastage by longitudinal splitting is obviously related to the use of timber in building or constructional work, and in this field the Building Research Board is making a steady advance Factors involved in weathering, the composition and properties of cement, the stresses and strength of constructional materials such as concrete, earth pressure, and the fatigue of materials, have received systematic investigation An experimental house has been used to correlate the heat requirements with weather conditions so as to obtain maximum efficiency from the point of view of the user

The work of the Illumination Research Committee is also closely connected with housing problems, as is that of a joint committee of the Fuel and Building Research Boards on Heating and Ventilation The former has directed investigations at the National Physical Laboratory on the effect of window size, colour, and reflection from walls and ceilings on the illumination of rooms, the effect of distribution and colour of various systems of lighting on clerical work, as well as investigations on street lighting and glare

The latter represents only one of the ways in which the work of the Department impinges on the important field of transport The establishment of a locomotive experimental station for tests and general research on locomotives, the testing of ship forms and propellers carried out in the William Froude National Tank, and the establishment of a second tank for research on ship design, resistance, and propulsion, etc , the aerodynamics research at the National Physical Laboratory, and the investigation of the Fuel Research Board on the

causes of fires on steamships in bunkers and cargo coal, are sufficient evidence of the important contributions made in every field of transport, without enumerating the metallurgical research or the important engineering investigations carried out at the National Physical Laboratory

In another field of communications, the Radio Research Board is making contributions which affect the millions of homes where broadcasting is received, while dental research, the production of insecticides for the destruction of the cocoa moth, the production of new drugs, and the discovery of the efficiency of borax—boric acid mixtures for the fireproofing of fabrics—and investigations on the action of sunlight on cotton, which have revealed the deleterious effect of small traces of iron, are all that can be mentioned of the activities of the Fabrics Research Board

Similar work is being carried out in Canada, Australia, New Zealand, South Africa, and in certain fields, notably in that of the transport of fruit and on the investigation of Empire timbers, much has already been done to secure co operation between the mother country and the Dominions overseas Even the above brief survey should make it sufficiently clear that the work of the Department of Scientific and Industrial Research is a vital factor in the prosperity of the British Empire, and upon its wise direction and active prosecution depend in large measure our prospects of restoring our industries to full vigour, exploiting to the full such natural advantages as we possess, and, by increased efficiency where we now possess no such advantages, recovering something of the position we formerly held amongst the industrial nations of the world

Physical and Mental Development of Children

IN spite of the assiduity with which the growing child has been studied within recent years, it cannot be said that we know very much about him But what we do know, and know with any degree of scientific certainty, is set forth in the Report of the Consultative Committee on the Primary School* recently issued The Committee, indeed, has spared no pains in securing the most trustworthy information at present available It has interviewed eighty nine witnesses, it has read a staggering number of memoranda it has examined with special care all evidence which can claim scientific validity Hence it has treated with special respect the opinions of physiologists and psychologists Indeed, much of what is said in the body of the Report about the development of the child is based on two memoranda which are printed in full in the appendix The first is by Prof H A Harris on the physical development of the child, and the second by Prof Cyril Burt on the mental development of the child

Prof Burt's memorandum will be dealt with first It may be said at once that it is wholly admirable It sets forth with great clearness, and with no small measure of charm, all that is certainly known about the psychology of the child of primary school age—all that would receive the unqualified support of the author's fellow psychologists in Europe and America It indicates the views that have survived, and these views show how far we have moved within the last thirty years

Thirty years ago, the orthodox creed was largely based on biology The belief of what happened in the mind was mixed up with a belief of what happened in the body and in its remote progenitors It was believed that in the growing child certain instincts and interests and powers remained virtually dormant up to a given age, and then suddenly woke up and became insistently active Their maturation was almost as sudden as their birth Thus definite layers of mental life were laid down and consolidated, and, on top of these, new layers were superimposed First came the mastery of the physical senses, then the control of the muscular system (including the muscles of speech) which give rise to walking, dancing, talking, and constructing things with the fingers Then came the development of memory, and finally the emergence of a capacity to reason

Mixed up with this stratification theory, as Prof Burt calls it, is the recapitulation theory, which states that the development of the child tends to reproduce in rapid and abbreviated form the evolution of the race He goes through the cave dwelling period, the savage period, and the barbarian period He is at various times in the hunting stage, the nomadic stage, the agricultural stage, the craft stage, and what not

We no longer hold these views—not in their original form at any rate The stratification theory is discredited by the fact that experiment has exploded the old doctrine of distinct faculties, such as memory and reason, and the recapitulation theory is discredited by the failure to find evidence for the transmission of personally acquired characters There is no more reason to think that the son of a potter inherits the aptitudes and interests of a potter (apart, that is, from the influences of his immediate environment) than there is for believing that the son of a mathematician will know the differential calculus by the light of Nature Indeed, these old beliefs have been shattered through their failure to fit in with the facts of the mental life which have been disclosed by direct observation and experiment For the method of direct study is essentially the modern method

This is an important point of methodology The child's mind is studied, not by studying his body, his brain, or his pedigree, but by the simple and obvious method of studying the thing itself The facts to be observed and explained are mental facts Real progress in the study of mental development may be said to have begun when the psychologist resolutely turned a blind eye to the alluring theories of the physiologist or the

* 'The Primary School' (London H M Stationery Office, 1931) 2s 6d net

anthropologist, and began to study the mind as a mind. It was Binet who set the investigator on the right track. His instrument of research was neither a scalpel nor a microscope, but a mental test—a simple examination question, so devised, so applied, and so interpreted, as to become at once a means of discovery and a means of measurement. Indeed, all we know with certainty about the mode and rate of development of the child mind is a result of the direct method of mental testing.

This is abundantly evident from Prof. Burt's memorandum. He shows how, by the modern method, it is demonstrated that general intelligence grows with age, that the so-called faculties are all mixed up together from the very start, and that special intellectual interests and abilities develop, though they do not begin, at successive ages of school life. The new findings wholly fail to confirm the old theories. There is no ground for the old belief that memory is stronger at the junior school period than at any other; nor yet for the old belief that children cannot reason until they reach the adolescent stage. Children of all ages are found to reason well enough within the range of their understanding.

Prof. Harris's memorandum is equally good of its kind; but is different in kind. It has more of personal theory and conjecture; it pushes out further into the realm of the unexplored. For this very reason, some of his views, interesting and suggestive as they are, must be accepted with caution. He lays much stress upon successive periods of springing up and of filling out that occur in the course of a child's growth. The child mainly grows in height at one period and mainly grows in weight at another. There are, according to Dr. Harris, three of each period. The second springing up period, for example, takes place during the ages of five, six, and seven years; and the second filling-out period during the ages of eight, nine, and ten. The curves of growth, however (one for height and one for weight), which he publishes in his memorandum, afford but slight evidence of these periods. Indeed, he admits that his inferences are drawn from clinical observations rather than from the curves of growth.

The existence of this rhythm is not denied; nor is the importance that Prof. Harris attaches to a recognition of this rhythm; but what is in doubt is whether it follows such simple laws as his classification suggests. A letter is at hand from a schoolmaster in Lancashire, who for many years made careful and regular measurements of his daughter's increase in height. For many years, beginning at the age of three, she grew at the rate of two inches a year—one inch in April and another inch in October—her stature being practically constant for the remaining months of the year. During the two growing months, she was mentally inert; and during the two months that respectively followed she often succumbed to the various illnesses incident to childhood. This, of course, is only one case; but other similar ones might be mentioned, which at least indicate that the rhythm is to a large extent individual and personal. If there is a wide wave of tendency over a long period, there are many ripples on the wave.

Prof. Harris shows clearly that sex differences appear all along the line, and not merely at adolescence. Indeed, it has long been an accepted fact that in the matter of physiological age, as judged by the eruption of teeth, the ossification of the wrist bones, and the onset of puberty, there is a difference between the two sexes which at the age of eleven amounts to about two years. Anatomically, a girl of eleven is at the same stage as a boy of thirteen. Here we find a clash of opinion between the physiologist and the psychologist. While the physiologist proclaims a wide disparity between the development of boys and the development of girls, the psychologist just as confidently proclaims their identity. He tells us that neither in the level nor in the rate of intellectual development is there any appreciable difference between boys and girls. There are emotional differences, and differences of interest; but no difference in general intellectual power. The truth, of course, is that each class of statements is valid in its own sphere. As boys and girls differ in muscular development, they should play apart; as they roughly agree in intellectual development, they may study together.

Each class of statement is valid in its own sphere; and Prof. Harris's valuable memorandum will be read with much interest and profit by all concerned with the nurture of the young. It is illustrated by excellent photographs; it is enlivened by wise and epigrammatic sayings; it is abundantly provocative of thought. It is only when he leaves his own territory and would base psychology on physiological facts that we join issue with him. He says, for example: "All growth and proliferation on the one hand and all differentiation for special function on the other will probably be found to be the ultimate basis of a rational psychology, whether it be labelled 'Gestalt' or not." As a pious belief we may let it remain. As a guide to psychological research, it seems to anyone who is familiar with the false clues of the past to stand on the same level of usefulness as the project of the Laputan philosopher to extract sunshine out of cucumbers.

P. B. Ballard.

Obituary

Dr. Enrico Sereni

The sudden death of Enrico Sereni, at Naples on Mar. 1, ends prematurely, at the age of thirty years, a career full of scientific usefulness and promise. Sereni had been in charge since 1926 of the section of physiology at the Zoological Station at Naples, and so was well known to the many biologists who worked there. To his British physiological friends and colleagues he was better known from having spent a large part of 1924 in London at University College, and from having travelled with them to and from the International Congress

of Physiology in Boston in 1929 He valued his connexion with Great Britain, and his friends will miss his frequent and cheerful greetings

Sereni took the degree of M D in 1922 with honours While still a student he had been awarded three scholarships for research work which he performed in the laboratory of human physiology in Rome After graduation, he obtained, in competition, a studentship from the Ministry of Education to work in Italy and abroad This was how he came to London, though he supported himself here, frugally enough, for a longer period than the studentship allowed, by working early and late, assisting a medical friend, so leaving the days free for the laboratory In 1923, he was appointed assistant in the Department of General Physiology in the University of Rome, and in 1925 *libero docente* From 1925 he gave, every year, in the University of Naples, a course of lectures on physiology for students of medicine and science In 1926 he was appointed to the position which he held when he died Before entering the University, Sereni had volunteered, at the age of seventeen years, for military service, serving as a lieutenant and gaining the Croce di Guerra

Sereni's researches extend over various fields of physiology His most important work deals with anaphylaxis, which he studied from a general biological point of view on men, on various animals, and particularly on tissue cultures He worked more recently on the humoral and nervous coordination in cephalopods and on the behaviour of unstriated muscle A V H

Mr J G Millais

Mr J G Millais, who died on Mar 24, the sixty-sixth anniversary of his birthday, was a man of many interests and talents A traveller and a sportsman, who followed big game on the continent of Europe, in Africa, and in North America, an artist and a naturalist, who could write discursively about the ways of wild life or particularly upon specific themes, he unified all these interests in authorship The variety of subjects of his published works is great, as the standard of his descriptions and accuracy is high, yet devotion to sport lay behind most of his writings

Millais' travel books are always interesting and contain many acute natural history observations His monographs, essential to the British naturalist, show a wonderful range of information "The Natural History of British Surface Feeding Ducks" (1902) was rounded off by two volumes on "British Diving Ducks" (1913), and in the interval he wrote "The Natural History of British Game Birds" (1909) Amongst mammals, he opened with a standard work on "British Deer and their Horns" (1897) and proceeded to the most important of all his books, "The Mammals of Great Britain and Ireland", published between 1904 and 1906 The three enormous volumes of this monograph, awkward to handle because of their bulk and weight, contain the best complete account of their subject we possess Latterly, Millais' interests concentrated upon the flower garden, and amongst his last publications are "Rhododendrons and their Hybrids", a series of three volumes running from 1917 to 1923, and 'Magnolias" (1927)

Millais inherited artistic ability from his father, Sir John Millais, and illustrated in full or contributed to the illustration of his own books, but his finished drawings are inclined to be rather stiff and hard in tone, and lack the freedom of line and spontaneity which characterise the pencil sketches he often reproduced J R

We regret to announce the following deaths

Dr J Anderson, formerly fellow of the London School of Tropical Medicine, later professor of medicine in the University of Hong kong and recently director of the division of medicine in the Henry Lister Institute at Shanghai, aged fifty two years

Prof R K Butchart, professor of mathematics in Raffles College, Singapore, and formerly professor of physics in Wilson College, Bombay, on Mar 30

Prof W C M'Intosh, F R S, emeritus professor of natural history in the University of St Andrews, distinguished by his work in marine biology, especially the systematic study of British marine annelids, on April 1, aged ninety four years

Senator R Nasini, professor of chemistry in the University of Pisa, on Mar 29, aged seventy five years

Prof Hugh Ryan professor of chemistry in the University College of Dublin and Chief State Chemist to the Irish Free State, on Mar 27, aged fifty seven years

News and Views.

The report of the Court of Inquiry into the loss of the airship *R101* over Beauvais on Oct 5, 1930, has just been issued (Cmd 3825 London H M Stationery Office 2s 6d net) It admits that an exact explanation of the immediate happenings leading to the disaster can never be given, owing to the lack of evidence, but by examining various hypotheses the Court has come to the unanimous conclusion that the one presented is the most plausible This is, that there was a rapid loss of gas from one of the main forward gas bags, added to a heaviness from a gradual leakage of gas due to attrition of the bags, probably greater than was suspected A heavy down air-current forced the nose down, and at the same time may have either caused or accelerated an existing tear in the outer envelope The rush of air through this, again, may have either initiated or extended a split in the inner bag It is known that the wind was variable enough to have buffeted the nose of the ship up and down, and the height coxswain, only just on duty and fresh to the 'feel' of the elevators, had possibly over corrected an upward deflection when the downward one caught him He then lost height to a dangerous extent while swinging the elevators to the other extreme position, but eventually succeeded in correcting the ship's altitude The further loss of height following this appears to have been intentional in an endeavour to make a

slow landing when it was realised that a crash was inevitable

THE other part of the report on the loss of *R101* is devoted to discussing the responsibility for the undertaking of the flight to India at that early stage in the ship's development. It is quite clear that although there were an exceptional number of novelties in design, there is no evidence of the failure of any of these having been either the cause of, or even contributory to, the disaster. On the other hand, the programme of flying trials as originally drawn up by the experts at Cardington had been curtailed. Since the addition of the extra bays, the ship had never flown in anything but exceptionally fine weather, and had never carried out speed trials. The airworthiness certificate, without which the flight could not have been undertaken, was apparently issued by the Air Ministry before the report by the Airworthiness of Airships panel upon which it should have been based, was even written. It is abundantly clear that considerations of policy were allowed to overrule all others in deciding that the flight should take place when it did although the blame lies with the system of controlling such work, rather than upon any particular individual.

ON Mar 31 at 11 2 A M (5 2 P M G M T), Managua, the capital of Nicaragua, was almost completely destroyed by a violent earthquake, many of the walls left standing after the shock and the fires that followed being thrown down by strong after shocks on Mar 31 at 9 15 P M and April 1 at 5 15 A M. The principal shock lasted only a few seconds. Estimates of the number of persons killed range from 500 to 2000, out of a population of about 50,000. Though great earthquakes are rather frequent in the Central American republics, it is in Guatemala and Salvador that they are most serious. During the eighteenth and nineteenth centuries, out of 30 very destructive earthquakes, 14 occurred in Salvador, 10 in Guatemala, 4 in Costa Rica, 1 in Honduras, and 1 in Nicaragua. According to Montessus, who has made a detailed study of Central American earthquakes, the most important seismic centres in Nicaragua are those of Leon and Granada, which are respectively 54 miles north and 26 miles south east of Managua. One of the few minor centres in the country lies close to Managua. The most interesting features of the recent earthquake are its brief duration, the comparative smallness of its area of damage, and its occurrence in an almost dormant seismic zone.

A GREAT advance has recently been made in the technique of radio telephony which promises some surprising developments in the near future. The International Telephone and Telegraph Laboratories have shown that it is possible to utilise Hertzian waves, the frequency of which is more than a hundred times greater than the most rapid at present in use. The new method utilises wave lengths of between 10 cm and 100 cm in length instead of the present 'short waves' which lie between 10 metres and 100 metres. The properties of the new 'micro rays' are approximately the same as those of light rays. They can be reflected and refracted by devices of an optical nature and travel in straight lines. The curvature of the earth and the altitude of the sending and receiving stations are the determining factors for the distance of transmission. It is necessary that the two stations should be visible from one another. Hence high sites will be the most desirable in the neighbourhood of populous centres. There appears, however, to be no limit to the number of relay stations that can be used. A demonstration of the new system was given on Mar 31 between officials and engineers on the cliffs at St Margaret's Bay, near Dover, and Blanc Nez, in France. The speech vibrations were applied to a micro radion tube in which oscillations of 1,600,000 kilocycles per second (about 17 cm) were generated. The modulated waves were sent in a straight line by a parabolic reflector 10 feet in diameter to a similar reflector in France, where they were concentrated on the receiver. The demonstration was entirely successful and proved the practical character of the micro ray method. The method provides a wave band nine times the width of that previously available. In addition, as the waves travel in straight lines and their distance range is restricted, a large number of stations can operate on the same wave length and the present congestion of the ether will be relieved.

THE International Telephone and Telegraph Laboratories have also to be congratulated on a notable achievement in the field of facsimile telegraphy. By the new method, pages of type, handwriting line drawings, and plans can be transmitted at the rate of two sheets a minute. In the case of typewritten sheets containing five hundred words, this corresponds to a speed of 60 000 words an hour. In the picture telegraphy at present in use between the Post Office and several continental cities, about twenty minutes is required for the transmission of a single picture. As in the case of other picture telegraphic systems, a device is used in the new method to scan the message in a series of fine parallel lines with a point of intense light. The light reflected from each elementary area of the sheet is collected and led to a photoelectric cell. This cell delivers to an amplifier a signal corresponding in amplitude to the tone value of the picture element, pure white giving a large signal and pure black a zero signal. At the receiving station a similar device is used, the message being replaced by a strip of photographic paper which is moved continuously forward with a speed equal to that of the message at the transmitting end. The beam of light is now obtained by an argon lamp which acts as a light valve. The motors operating the scanning heads are controlled by means of tuning forks. A full description of the method is given in the *Electrician* for April 3. The method is particularly useful for telegraphing languages like Chinese, which have to be rewritten in some alphabetic language before being sent by the Morse code in ordinary telegraphy.

THE Marconi Company has received orders for the erection of a chain of wireless transmitting and receiving stations through the heart of Africa. The stations

have been ordered by the Administrations of Uganda, Kenya Colony, Tanganyika, Northern Rhodesia, Southern Rhodesia, and the Union of South Africa, and they will be used both for the operation of the new Cape to Cairo air route and, in many cases, for general communication. The apparatus to be installed will be for transmission and reception on medium and short wave lengths. When these stations are completed the trans-African aviation service will be the most highly organised long-distance air route in the world, and at the same time internal and external communications will be greatly facilitated throughout the continent. The sites for the stations are to be in the proximity of Kampala (Uganda); Nairobi (Kenya Colony); Moshi, Dodoma, and Mbeya (Tanganyika); Mpika and Broken Hill (Northern Rhodesia); Salisbury and Bulawayo (Southern Rhodesia); Germiston, Victoria West, and Cape Town (Union of South Africa). The wave-lengths used for wireless communication between the aircraft and these stations will be 900 metres, and inter-aerodrome communication will take place on short waves. For general communications, special wave-lengths have been allotted to the stations at Mpika, Broken Hill, Bulawayo, Salisbury, Germiston, and Victoria West, which will be used for this purpose.

IN a dispatch from the Peking correspondent of the *Times* which appeared in the issue of Mar. 30, attention is directed to the manner in which, it is alleged, a Society for the Protection of Ancient Relics, formed some two or three years ago in Peking, is interpreting its functions. The scope of the society is wide, for it covers objects ranging from works of art to fossils. It is semi-official and has the approval of the Nanking Government. Its methods are said to be the subject of much criticism. Apparently the latest object of its attack is Sir Aurel Stein, whose expulsion from Chinese Turkestan, where he is now engaged in exploration, is said to be demanded on the grounds that while he was raising funds in the United States he spoke slightingly of the new China, and that his funds are too large for his purpose, which must have an ulterior and, it is presumed, political object. It will be remembered that Dr. Roy Chapman Andrews experienced obstruction on the return of the Fourth Central Asiatic Expedition from Mongolia, and in the following year the expedition had to be abandoned owing to the delay over the negotiations about the conditions on which the expedition would be allowed to proceed and the Chinese personnel to be attached to it. It is said to have been alleged at the time that Dr. Andrews's expedition was no more than a cover for a search for oil. It is scarcely necessary for us to defend Sir Aurel Stein from these charges, nor the further charge that it was his intention to smuggle out of Chinese Turkestan any antiquities that he might find. The declaration made by him before he entered the country, and forwarded to the authorities by the British Ambassador in Peking, is a sufficient guarantee of good faith, were one needed. Nor is it necessary to enter into the charge against the American expedition, even if there were any evidence before us.

THERE can be no question, however, that the ill-advised publicity given to the character of the material found by the American Central Asiatic Expedition—the dinosaurs' eggs—and the equally injudiciously advertised attempts to raise funds by their sale, aroused the suspicions of the Chinese and impressed upon the less well informed that something of enormous value was being taken out of the country. It was in precisely similar circumstances that the recent legislation relating to antiquities in Egypt was passed. If the Peking Society is animated, not by a hatred of the 'foreign devil', but by a genuine desire to preserve China's antiquities for China, this is a perfectly legitimate aspiration, recognised as the right of nearly every civilised country, even England—or at least it will be in some degree when the new Ancient Monuments legislation is in force. If this desire is not genuine, as the *Times* correspondent suggests, then an attempt should be made to arrange a *modus vivendi*. It is admitted that, in addition to official personages, the society consists largely of the officials of universities, museums, libraries, research institutes, and the like. A great deal of archæological work has already been carried out in China by Europeans, and we have it on the authority of Prof. Elliot Smith in regard to the latest and greatest discovery of all, the Peking skull, that individual Chinese drawn from the classes which compose the society have co-operated wholeheartedly in organising the work of the geological survey which led up to the discovery of the skull, in the actual discovery, and in the work of preparation in the laboratory with Dr. Andersson, Dr. Davidson Black, Prof. Elliot Smith himself, and others of non-Chinese nationality, who have assisted them from time to time.

MR. BERTRAM THOMAS has been awarded the Founder's Medal of the Royal Geographical Society and also the Burton Memorial Medal of the Royal Asiatic Society, in recognition of his work of exploration in the Great Sandy Desert of Arabia. It is also announced that Mr. Thomas has accepted the invitation to deliver the triennial Burton Memorial Lecture before the Royal Asiatic Society on his return to England. At the close of the War, Mr. Thomas was a political officer in Mesopotamia, and his knowledge of the country and his understanding of tribal Arab character proved of signal service to the administration under Sir Arnold Wilson in the troubled years which followed. After serving in the same capacity in Transjordania, he was selected to be the Financial Adviser and Vizier of the Sultan of Muscat and Oman, being the first Englishman to hold such an office, virtually that of Prime Minister. Both in the course of his official duties and in his leisure, Mr. Thomas has explored some thousand miles of the Oman coast in his patrol boat, while his relations with the turbulent tribes of the littoral have enabled him to penetrate country unknown to Europeans, adding considerably to our geographical, ethnological, and linguistic knowledge of Arabia. An account of his last journey appeared in the *Times* only a week or two ago. His first two journeys in Arabia, of which the scientific results were published in the *Geographical Journal*, the *Journal of the*

Royal Anthropological Institute, and other periodicals, have been pronounced by competent authority to be the most important and extensive piece of geographical exploration carried out since the War

The various organisations connected with research in the textile industries have now reached the stage where much of their work is suitable for direct application to the immediate problems of the industry itself The recent Report of the Council of the Wool Industries Research Association (formerly known as the British Research Association for the Woollen and Worsted Industries) gives a concise summary of the application of the work of that Association to woollen and worsted spinning and to dyeing and finishing processes The Association has, during the past year, continued fundamental research on biological, chemical, and physical problems It has also devoted much time to the examination of the inherent characteristics of the wool fibre, its response to processing, and the possibilities of its utilisation in directions which are as yet undeveloped The report records that in the course of electrical investigations, methods have been devised for the prevention of electrification during the processing of wool, and that the use of wool as an electrical insulator has now become an accomplished fact It further adds that not inconsiderable quantities of worsted yarn have recently left Bradford to be employed for electrical insulation purposes in cable manufacture There is much scope for this research association, and if its new method of financial support by means of a voluntary levy on the industry becomes really successful, its utility to the wool textile industry should be considerably enhanced

The *Journal* of the National Institute of Industrial Psychology, Vol 5, No 5, contains an account of "The Organisation of Works Transport", an investigation carried out by Messrs L I Hunt, W H O'N Manning, and G H Miles The problem confronting the investigators was one of hand trucking in a machine producing works housed in an antiquated building The whole transport system was carefully studied The fluctuating demands of 38 departments and the irregular flow of production along 231 connecting routes were considered Sources of delay were noted, and a comprehensive scheme of reorganisation initiated, this comprised the classifying of routes and their co-ordination under a central transport office A system of circuits, combining all routes, except those with the heaviest loads, enabled a scheduled service to the departments to be maintained Very definite results followed the introduction of the scheme The economy of labour amounted to 60 per cent, one man handling 50 instead of 20 loads, labour costs were reduced by 40 per cent, yet labourers' earnings rose, and an efficient, flexible transport system replaced the old cumbersome one This experiment has been industrially successful, but its scientific value is considerably reduced by the number of variables that have been introduced The arrangement for a bonus payable on individual output and working time follows on in the Taylor Gilbreth tradition and perpetuates the same fallacy In spite of this, however, many interesting points emerge, and Mr Hunt's exposition is admirably concise and lucid

Mr S Morris Bower, of Langley Terrace, Oakes, Huddersfield, is asking for help in extending a statistical inquiry into the frequency of thunderstorms in the British Isles in winter, which was originated by Mr C J P Cave in 1916 and was concluded in March 1929, to a similar inquiry for the six months April to September What is required is a note of the place, date, and time of occurrence of thunder, lightning, or hail, with the direction in which the lightning was seen Additional details, such as the time of commencement of very heavy rain or hail, should such occur, and of the direction of movement of any well developed storm, would be welcome Thunderstorms sometimes move across the country along a definite 'front' that is to say, if crosses are marked upon a map showing where storms occurred at a particular hour, these form a nearly continuous chain, when similar information is shown for a later hour, a similar chain of crosses is normally shown, but displaced from the position that the first chain occupied Phenomena of this kind are readily studied by professional meteorologists at the Meteorological Office with the aid of synoptic weather charts But it is only on a small number of days in the year that anything of this kind is to be found on the synoptic charts Numerous storms, more or less isolated, often occur both in winter and summer They may travel or remain nearly stationary throughout their life history, in the latter case especially they often lie too far from any official reporting station for their occurrence to be noted officially It is especially in regard to this class of storm that an organised inquiry is of value, and until such an inquiry has provided a reasonably complete statement of the facts, there is little prospect of being able to give a satisfactory general account of the thunderstorms of the British Isles

The arrangements for the British Chemical Plant Exhibition to be held on July 13–18 at the Central Hall, Westminster, in conjunction with the jubilee celebrations of the Society of Chemical Industry, regarding which a preliminary announcement was made in Nature of Jan 17, are making rapid progress About forty firms have already booked space, and since these include most of the important firms in the British chemical plant industry, the success of the exhibition is assured The exhibits will cover the whole range of the industry The arrangements which the Chemical Engineering Group of the Society of Chemical Industry is making for the Section showing, on a co-operative basis, the work of the various research associations and of the Department of Scientific and Industrial Research are also well advanced The scheme is being supported by the Department, which will be represented by the National Physical Laboratory, the Chemical Research Laboratory, the Fuel Research Board, the Forest Products Research Laboratory, and the Building Research Board The research associations dealing with the following industries will co-operate boots, shoes, and allied trades, cast iron,

leather, linen, non ferrous metals, paint, colour, and varnish, rubber, wool There will be three main groups, dealing respectively with (1) materials used in chemical engineering, such as metals, fabrics, etc, (2) chemical plant and associated equipment, including that employed on fuel, and (3) testing apparatus and standardisation

So long as mountain peaks remain unscaled by man there will be found hardy adventurers to attempt them, for the glory of achievement as well as for the valuable scientific data which well organised expeditions afford In 1924 there was the last Everest expedition, which ended so tragically with the death of Mr G L Mallory and Mr A C Irvine Last year saw the attempt on Kanchenjunga led by Dr Dyhrenfurth, when the climbers reached Jonsong Peak (24,344 ft) Now we have a British expedition, consisting of Mr F S Smythe (leader), Capt E St J Birnie, Dr R Greene, Mr R L Holdsworth, and Mr E E Shipton, which will attempt Mount Kamet (25,447 ft) According to the *Times* of April 4, the party left Venice on that day for India Mount Kamet is in the Gharwal District of the United Provinces and is in the Zaskar Range, a northern branch from the main Himalayan chain The approach to Mount Kamet will take the expedition across the watershed separating the principal sources of the Ganges, to the glaciers above Gangotri, which is to the east of the main peak, and it is expected to obtain valuable topographical, physiological, botanical, and other data and useful climbing experience There have been several attempts on Mount Kamet in the past, the last being in 1920, so the present expedition should have the advantage of knowledge of local conditions

THE great heights of many of the blocks of buildings recently erected in America and picturesquely called skyscrapers has led to the development of high speed lifts In the *Westinghouse International* for the first quarter of 1931, a description of Carew's Tower, Cincinnati's largest structure, is given It combines a 48 story office building, a 28 story hotel, a 25 story garage, and many retail shops Three floors in the office building are reserved exclusively for doctors and dentists Forty one lifts are required, including six of the fastest in the world, to make life in this self contained city possible The express lifts move at a speed of 900 feet per minute, which is a little greater than ten miles per hour The speed of the local lifts is 700 feet per minute The hotel contains a thousand rooms and is served by nine lifts, six passenger and three service There are three large motor-car lifts serving the parking garage Their speed is altered by varying the applied voltage, thus eliminating mechanical gear They can make a flight up the 25 floors in about half a minute The stores use lifts moving at 450 feet per minute At still slower speeds, dumbwaiters, sidewalk lifts, a 12 5 ton hydraulic lift, and an observatory tower lift operate At speeds of 500 feet and above it is practically impossible to read the numbers on the various floors Lifts for speeds up to 1200 feet per minute are being designed, and at present there seems nothing to stop still higher buildings and still faster lifts from being constructed A description of the lifts used to carry the students from one lecture room to another in the University of Pittsburgh, which is 40 stories high, is also given

SEVERAL special problems have arisen in connexion with the supply of direct current to traction systems Two solutions are in use and they are advancing in widely diverging directions In America, the method of converting alternating current into direct current in the automatic substations is to use machinery of the rotating converter type In Europe the use of mercury arc rectifiers is rapidly extending In a paper read to the Institution of Electrical Engineers on Mar 12, by J W Rissik and H Rissik, the special requirements of traction operation were outlined and the present state of development of the ironclad rectifier for traction use, as reflected in its applications in converting substations on the Continent, was described Since the War, the use of rectifiers in Germany has extended very rapidly The whole of the Berlin city and suburban railway system is supplied by rectifiers in 47 substations, 31 being controlled from a distance The German federal railways have adopted the rectifier as the standard equipment for traction substations The development of rectifiers in America has been comparatively slow, the rectifiers manufactured there are generally designed in accordance with the latest European practice In Great Britain the increased demand has stimulated manufacturers to compete with foreign firms by improving their designs The authors believe that in the scheme of general railway electrification which will eventually be carried out in Great Britain, rectifiers will be used, if not exclusively, then very largely They think that in the next decade Great Britain will be placed in a position comparable with that which now obtains in Germany

WRITING on "Chemistry as a Career", in the *Alumnus Chronicle* of the University of St Andrews, Prof John Read remarks on the current tendency in certain secondary or public schools to carry specialisation too far with apt pupils This tendency appears to be largely a response to the requirements of some of the universities in their entrance scholarship examinations Hence many such pupils acquire little or no knowledge of biology, whilst others are deficient in English, modern languages, mathematics, and other fundamental subjects Prof Read wisely advocates that a pupil should be restrained from inordinate specialisation, until he has secured the necessary basis of a well proportioned general education, and he supports the adoption of a broader test of intelligence and merit than that now imposed on scholarship candidates In the same article, Prof Read explains the complex nature of the chemical profession and surveys the prospects which confront entrants He points out that chemistry provides a multitude of diverse professions, rather than a single homogeneous profession, and that in doing so it provides scope for all sorts and conditions of chemists Just as it is difficult to legislate effectively for the com-

plex racial association of the British Empire, so the complex corporation of chemists is unable to safeguard the interests of the profession in a generally acceptable manner Whilst specialisation at an early stage is undesirable, it is nevertheless essential later, and it is evident that at present there is no overproduction of chemical specialists of first class ability On the other hand, it is difficult to find openings in chemical industry for men of second class attainments or for women chemists possessing the highest qualifications Prof Read pays a deserved tribute to the late Lord Melchett's policy in advancing the career of industrial science, in a scientifically organised chemical corporation with trained chemists in the highest administrative positions and on the board of control, the chemist is no longer the factory 'maid of all work' Expansion of schools of organic research in the British universities in response to demands formulated under the shelter of the Dyestuffs Act has also opened attractive and useful scientific careers

THE biological interests of the Galapagos Islands are so many that it is strange that no thorough exploration of their inhabitants had been carried out since Charles Darwin made them famous, until the islands were visited by the expedition, planned by L M Loomis, formerly director of the California Academy of Sciences, which remained in the field for more than seventeen months during 1905 6 An account of the work of the expedition, by Joseph R Slevin now appears as one of the *Occasional Papers* of the California Academy of Sciences, under the title "Log of the Schooner *Academy*" It is an interesting story The study of the land tortoises, of which 266 specimens were collected showed that, contrary to belief, they still inhabited all the islands in the archipelago from which they were formerly known (except Charles Island), and that they even existed on islands where they were never before observed But many minor biological points attracted the attention of the explorers The tameness of birds and lizards was remarkable both would come to pick up crumbs dropped beside the observer, both, alas! were rewarded by being killed with a switch The lack of sensitiveness possessed by lower animals was well shown when, on a lizard's tail being severed by a knife, the animal did not move until, seeing the wriggling severed portion, it turned about and grabbed it as if it were a foreign object Land iguanas were common on Narborough Island and occurred over the whole area, even to the rim of the crater at an altitude of 5000 feet, and the wild goats on Hood Island, feral descendants of domestic stock, quenched their thirst by drinking sea water on the beach

AT the meeting of the London Mathematical Society on Thursday, May 14, at Burlington House at 5 P M, Prof J E Lennard Jones will deliver a lecture on "Quantum Mechanics of Atoms and Molecules" Members of other scientific societies who may be interested are invited to attend

HIS MAJESTY THE KING has been pleased to approve the award of the Royal Medals of the Royal Geographical Society as follows *Founder's Medal* to Mr. Bertram S Thomas, for his geographical work in Arabia and successful crossing of the Ruba el Khali, *Patron's Medal* to Rear Admiral Richard E Byrd, U S N, for his expedition to the Antarctic, and his flights over both north and south poles

THE first of a series of demonstrations of horticultural machinery is announced in the Mar 26 issue of the Ministry of Agriculture's weekly publications The trials took place recently at Pinhoe, Devon, on a mixed fruit plantation kept in a high state of cultivation The implements used were the Simar Rototiller Nos 3 and 5 and the 'Monotrack' motor cultivator, the Planet Junior (garden tractor), the Gravely motor cultivator, and the Auto Culto motor cultivators, two types of the latter machine being used, one fitted with tines and the other with a 'one way' plough All implements, except the Simar 5 and the Auto Culto motor with plough, carried out cultivation between strawberry rows, the distance between the rows being about 2 ft 6 in Later in the day all implements except the Auto Culto plough worked among raspberry canes, the width cultivated being about the same (2 ft 6 in) The Auto Culto ploughed on land from which broccoli crop had been taken The demonstration, which was very well attended and carried out under favourable weather and soil conditions, proved entirely successful, all implements working successfully

THE subject selected by the Exhibition Committee for this year's exhibition at the Royal Institute of British Architects is "The Architecture of Modern Transport" It will consist of photographs, drawings, and models of architectural and decorative subjects connected with modern transport, and is intended to illustrate the latest developments both in Europe and America The types of work will include railway stations, signal boxes, various types of railway coaches, docks, harbour works, canal power stations and locks, liners and yachts, bus and coach stations, garages and filling stations, trams, buses, charabancs and private cars, bridges and viaducts, pylons, traffic control stations, hangars and aerodromes, aeroplanes and airships, lifts and moving stairways The exhibition will be formally opened by Mr H G Wells on April 21, at 3 P M, and it will remain open until May 22 Admission will be free

ANOTHER of the well-known and valuable catalogues (No 443) of Messrs Bernard Quaritch, Ltd, 11 Grafton Street, W 1, has reached us It gives the titles of, and in many instances useful bibliographic notes upon, upwards of 1500 works on botany, agriculture, forestry, fruit culture, gardens and gardening, herbals, early medicine and surgery, tobacco, etc, and should be obtained by collectors

MESSRS Dulau and Co, Ltd, 32 Old Bond Street, W 1, have just issued Catalogue No 183 of some 695 second-hand books on gardening and botany, including materia medica, pharmacy, perfumery and scent, from the libraries of the late Mr E M Holmes, curator of the Museum of the Pharmaceutical Society, and the

late Mr W Davis, collector for Messrs Veitch The same firm has also circulated a short handy list of useful books on gardening Both catalogues may be had free of charge on application

A CLASSIFIED list of second-hand instruments has recently been published by Messrs C Baker, 244 High Holborn, London, W C 1 The list is divided into ten sections, comprising microscopes and cognate apparatus, surveying instruments, astronomical instruments, spectroscopes, projection apparatus, including lanterns, slides, and projection microscopes, field glasses, chronometers, anemometers, thermometers, barometers, balances, hydrometers, various kinds of physical apparatus, such as polariscopes, voltmeters, and galvanometers, and photographic apparatus Apparatus can also be had on approval or on hire

APPLICATIONS are invited for the following appointments, on or before the dates mentioned —A sugar-cane mycologist and a research assistant each at the Agricultural Research Institute, Pusa India, for research into mosaic and other diseases of sugar cane —The High Commissioner for India (General Department), India House, Aldwych, W C 2 (April 20) A lecturer in geography at the Portsmouth Municipal College—The Secretary, Offices for Higher Education, Municipal College, Portsmouth (April 25) A lecturer in metallurgy at the Bradford Technical College—The Principal, Technical College, Bradford (April 30) A lecturer in philosophy at Armstrong College, Newcastle upon Tyne—The Registrar, Armstrong College, Newcastle upon Tyne (May 2) A draughtsman under the Ministry of Agriculture and Fisheries—The Secretary, Civil Service Commission, Burlington Gardens, W 1 (May 7) A chief research worker in the Nutrition Research Laboratories of the Indian Research Fund Association—The Secretary, Indian Research Fund Association, Simla, India (June 1) Teachers of woodwork under the Kent Education Committee—The Director of Education, Springfield, Maidstone A handicraft teacher (wood and metal work) under the Norfolk Education Committee The Secretary, County Education Office Stracey Road, Norwich

Our Astronomical Column

Comets —Prof G van Biesbroeck records, in *Pop Astr* for March, a remarkable increase of light in comet Schwassmann Wachmann (1), which passed perihelion nearly six years ago, and is now more than seven units from the sun In the middle of January, its magnitude was 17½, but on Feb 11 it had risen to 12½, thus showing a hundred fold increase in the light There was a somewhat similar, but less intense, outburst in December 1929, the magnitude then rising from 17 to 13½ Both the outbursts were short lived, the additional light fading after a few days It would seem that the cause of the outbursts must be sought in the comet's nucleus, rather than in the sun, but its nature remains a mystery A somewhat parallel case was presented by the two successive outbursts of light of Holmes's comet, at its first apparition in 1892 That comet was, however, much nearer to the sun, less than three units

Prof van Biesbroeck continued his observations of three other comets during February Stearn's comet has now been observed for four years, and is distant from the sun 11½ units, establishing a record in that respect Beyer's comet is still of magnitude 14½, and promises to be visible for several months more Comet Tempel (2) has been observed for six months, but is now lost in the sun's rays

Prof Nakamura gives some more details, in Kwasan *Bulletin* 192, of the object that he discovered last November it was called comet 1930 *g*, but it may be a minor planet, it looked quite sharp on some days, but on others had a nebulous appearance Positions are given for Nov 16, 17, and 18, plates were exposed on it until Nov 28, but it faded rapidly, and no images have yet been detected after Nov 18

The search for Encke's comet has been fruitless, it must now be left to southern observers to pick it up after perihelion passage, which occurs on June 3 It will be too near the sun until then to make detection possible

Distances of the Cepheid Variables —Very wide use has been made of the principle, first discovered by Prof H Shapley and his assistants, that the period of variation of a Cepheid gives a measure of its absolute magnitude, and consequently of its distance The distances of the globular clusters and of the spiral nebulæ are chiefly based on this method The graduation of the scale of absolute magnitudes involves the finding of the distances of the nearer Cepheids, this is a difficult matter, as they are too distant to obtain accurate trigonometrical parallaxes Estimates were made from their proper motions, but as these are small, it was known that the adopted values are subject to correction *Ast Jour*, No 951, contains a new discussion of their distances by B P Gerasimovic He redetermines the proper motions with the aid of recent catalogues, and also makes some use of the radial velocities, using the radial motion due to galactic rotation in the same manner that Dr J S Plaskett has done for the *B* and *O* stars He finds that for stars with period 4 days, Shapley's absolute magnitudes need to be increased (that is, made fainter) by 0 9 magnitude, while for 8 day and 16 day periods the increases are 0 8 and 1 2 magnitudes He adopts 1 0 magnitude in the mean as the average increase needed for the Shapley absolute magnitudes This implies that distances found from the Shapley curve need to be reduced in the ratio 0 631 to 1, or about 5 to 8 R E Wilson had suggested 0 7 to 1, which is in fair accord, but the much more drastic reduction of Shapley's distances in the ratio of 0 13 to 1, suggested by Curtis, Kapteyn, and van Rhijn about ten years ago, is shown to be improbable

Pluto —A further article on Pluto by Prof H N Russell appears both in the February number of the *Scientific American* and the February number of the *Journal* of the Royal Astronomical Society of Canada It describes the barycentric orbit, deduced by Nicholson and Mayall as a simple method of allowing for the greater part of the action of the other planets upon it Their period is 247 69 years, which is so close to 1½ times Neptune's period that it will need an interval of some 40,000 years to elapse before Pluto and Neptune are at their minimum distance from each other The work of Nicholson and Mayall indicates that Pluto's mass is probably comparable with that of the earth Prof Russell notes that if Pluto's albedo is the same as that of the lunar maria, its diameter would be about equal to that of the earth.

Research Items

Ancient Man in the Gipping-Orwell Valley—The *Proceedings* of the Prehistoric Society of East Anglia for 1930, vol 6, pt 3, contains a study of the deeply buried deposits of the non tidal valley of the Gipping above Ipswich and the tidal part of the valley of the Orwell below Ipswich These deposits lie in deeply cut and steep sided channels, filled apparently with glacial material buried beneath the deposits lying on the floor of the present valley They are evidently of high antiquity (I) The Gipping Valley (1) After the retreat of the ice which laid down the Upper Chalky Boulder Clay (third glacial epoch of East Anglia) and while climatic conditions were still severe, Aurignacian peoples were living in the valley Afterwards 11 ft of gravel was laid down, with an increase of cold conditions It is possible that one bed represents the fourth glacial epoch of East Anglia, and that the flint implements it contains were swept down and redeposited over the slightly less old implements found beneath (2) The Flood Plain Terrace In ascending order are encountered (a) a Combe Capelle floor of Early Mousterian age, (b) Early Solutrean, fine flint blades in loam belonging to the third inter glacial period below Flood Plain gravel Mammalian bones, among them the mammoth, belong possibly to this horizon (3) The gravel of the Flood Plain Terrace of post Early Solutrean age contains a large number of derivative flakes and implements, to be associated with the passing away of the fourth glacial epoch, the Boulder Clay of which contains implements of upper palæolithic type (4) The beds above the Flood Plain Terrace From the loamy peat deposit have been recovered a number of long, thin blades of flint probably of Magdalenian age (II) The tidal portion of the Orwell Valley Overlying the basal gravel is a bed of compact peat from which it is probable there came a skull comparable with the Tilbury skull and possibly contemporary with the Combe Capelle type of implement Above the lower peat is a shingly gravel capped by peat and mud in alternate layers From the base of the alluvium probably came implements exhibiting affinities with the Magdalenian In both the Gipping and Orwell valleys the neolithic period is represented, both geologically and archæologically only in the superficial beds

Song of the Skylark There have been many opinions expressed as to the length of time occupied by the song of a skylark Opinions would have been fewer and more consistent had each observer taken the trouble to time more than a thousand songs, as Noble Rollin did before writing a short paper on the subject (*Scottish Naturalist*, 1931, p 47) Variations in length occur according to the time of day, the month of the year, and the idiosyncrasy of the birds themselves, so that the range runs from 1 to 19 minutes But the average length was only 2 22 minutes A series of graphs illustrates time variation in successive songs, the average length of song for each month (ranging from 1½ minutes in July to 3 minutes in September), and the percentage occurrences of various song lengths in different months

Intelligence of a Raccoon—Experimental tests made by Prof Wm McDougall with the object of discovering whether a raccoon was capable of foresight are recorded in a *Daily Science Bulletin* issued by Science Service, of Washington, D C The animal was trained to look in a box for food Then a latch was put upon the box, pivoted on a screw so that a light push in the right direction would release the lid The raccoon having unsuccessfully tried to raise the latched lid, in a few seconds opened the latch and secured the food One by one, other latches were added, each new latch in the series holding the one attached previously, so that each had to be released in order before the next could be moved Thus a complicated series of 24 latches was built up, extending all round the box After the first few attempts, the raccoon never attempted to reach the food directly, but attacked the latches at once, and so efficient did she become that she was able to manipulate the series of 24 and open the box in a few seconds When some of the series were left open, she would pass them by untouched, in order to proceed to the closed latches Prof McDougall, whose full report will appear in the *Journal of Comparative Psychology*, regards the behaviour of the raccoon as showing that its actions were governed by foresight of the result of the actions

Bacteria in the Sea—Miss Blodwen Lloyd in her paper "Bacteria of the Clyde Sea Area a Quantitative Investigation" (*Journal of the Marine Biological Association of the United Kingdom*, **16**, 3, 1930) summarises her results of sampling three stations at regular intervals over a period of one year, together with further occasional samples from other localities The stations chosen were at Loch Striven, Loch Long, and Greenock, representing areas respectively free from pollution, moderately free, and highly polluted The apparatus used for vertical sampling is simple and the technique for the routine work follows as nearly as possible the procedure recommended by the American Society of Bacteriologists for standard examination of water, with some modifications The incubation temperature was lower by some six to twelve degrees than that usually employed, in order to encourage the growth of true water bacteria and to discourage other bacteria which thrive at higher temperatures The counts were made directly and the dilution method was not used The largest number of bacteria was found in the surface waters, decreasing with increasing depth until, at the bottom, there was a slight increase The numbers were remarkably constant throughout the year for all layers, with only slight evidence of rhythmic variations, except at the surface, where the numbers fluctuated considerably In the daytime the bacteria at the surface are irregular in number, but in the lower levels there is a slight increase during darkness Loch Striven and Loch Long are very free from pollution, but in Cumbrae Deep and in the estuary off Greenock the numbers are high, with a large proportion of what are presumably coliform bacteria

Alcyonaria of the Faroes—The Alcyonaria of the Faroes are for the first time described in detail by Dr P L Kramp ("Zoology of the Faroes", edited by Ad S Jensen, W Sundbeck, and Th Mortensen 1930 Vald Pedersens) Six species of Alcyonaria are known from the Faroes, all mainly boreal, and from the deeper water, about 400 650 metres around the Faroe plateau, five more are added The two littoral species *Alcyonium digitatum* and *Virgularia mirabilis* are very common, having their principal area of distribution south of the Faroes, but they are also found somewhat farther north *Alcyonium* likes a hard bottom and *Virgularia* likes a soft bottom No species with distinctly northern distribution has been found on the Faroe plateau The gorgonacean, *Stenogorgia borealis*, was named, but not described, in 1915 by the late Prof Jungersen in "Conspectus Faunæ Groenlandicæ" Dr Kramp, who has examined all Prof Jungersen's material, now describes this species in detail with good figures It differs from

other species of the genus in the tentacles being always completely destitute of spicules, but it closely resembles them in many other ways and undoubtedly belongs to this genus

Rafinesque's Types of Helices —H A Pilsbry (*Proc Acad Nat Sci*, Philadelphia, 82, pp 321 326, 1930) discusses the types of Rafinesque's genera of Helices Rafinesque published in 1818 a list of generic names, without descriptions or species, which was therefore of only historic interest The terrestrial genera were *Limax*, *Helix*, and seven new genera which he described in two papers, one in 1819 and the other in 1831 Mr Pilsbry considers each genus in turn, and indicates the species he considers should be taken as the type for those genera which are held to be valid For the genus *Aplodon* with three nodose whorls no satisfactory explanation has hitherto been forthcoming, for, as Mr Pilsbry points out, there is no shell in Kentucky (the area from which Rafinesque collected) which offers the slightest approach to the description But if it be supposed that Rafinesque had a stray marine shell among his Kentucky collections, the case becomes clear, for the description applies perfectly to the common species *Modulus modulus* (L) from Florida and the West Indies Mr Pilsbry is in no doubt as to the identity, and as *Aplodon* is prior to *Modulus*, he suggests that the generic name of the common marine shell be changed accordingly

Fresh-water Diatoms —The survey of fresh water Bacillariales of Devonshire by G T Harris (*Trans* of the Dev Assoc for the Advancement of Science, Lit, and Art, 1930) represents a large amount of work, extending over four or five years The field is one to which little attention has been paid and it would be interesting to know how surveys of other counties would compare with Devonshire Harris records 232 species from Devon, whilst West and Fritsch in the last edition of "Freshwater Algæ" say that about 250 species occur in the British area, which suggests that either Devon is extremely rich in species or else that the total number for Britain should be considerably higher In connexion with this, it may be significant that Harris finds the majority of the species more or less indifferent to habitat, so that it is possible that the diatom floras of different parts of the country might show less variation than is found in the case of other groups of plants As the number of species of diatoms is so large, the author is certainly wise, at this stage, to limit the records to well defined species and not to multiply the number by including doubtful species or by taking into account varietal differences

Significance of Relative Sexuality —Max Hartmann gives an interesting survey of the possible influence of external and internal factors on sex determination in Thallophyta in *Die Naturwissenschaften*, Heft 1, 1931 The facts bring out clearly the bi sexual potentialities of the sexual cells or gametes, but the fact that one sex always dominates, suggests that some realising factor is superposed, so that, regardless of external factors, any sexual cell has a definite tendency towards a particular sex The realising factor may be unequally distributed at meiosis, a clear example of which is *Gonium pectorale*, in which the four-celled cœnobium is built up of two cells of male tendency and two of female In this, and in the majority of cases, the sex appears to be fixed, though in some cases the sexual cells may occur in such close relationship to one another that it would be interesting to know what determines the behaviour Examples of *Achlya americana* have been observed in which the antheridial tube originated from an oogonium, and also others in which an antheridial tube, after fertilising an oogonium, grew on and produced a terminal oogonium Very interesting, from this point of view, is the work of Hartmann on *Ectocarpus siliculosus*, and of Jollos on *Dasycladus clavæformis*, where, by testing the gametes from different plants in various combinations it was shown that not only could they be grouped as male or female, but these groups could be subdivided according to the intensity of the sexual tendency Still further, if gametes of the same sex but of sufficiently different intensities were brought together, the gamete of weak intensity might actually behave as one of the opposite sex and copulation take place These two algæ present a good illustration of the bisexual potentialities of sexual cells and of the fact that normally the dominant sex is determined by some internal factor, but if this 'realising' factor is weak, then an external factor, such as the proximity of another gamete of stronger sexual tendency, may actually determine the behaviour So that we have here a typical example of relative sexuality

Soil Sterilisation —The value of soil sterilisation (or more strictly speaking, partial sterilisation) for the control of injurious insects and fungi and for effecting changes that lead to better cropping has proved so considerable that, at the invitation of the Ministry of Agriculture, Dr W F Bewley has prepared a bulletin on the subject entitled "Practical Soil Sterilisation" Growers of glasshouse produce no longer regard these operations as expensive luxuries and in market garden and propagation work they may also be carried out with advantage Sterilisation can be effected either by steaming, baking, or treatment with chemicals such as cresylic acid or formaldehyde, but of these the steaming method is the most strongly recommended, treatment once in four years being sufficient Baking is also reliable when the quantity of soil is relatively small Chemical treatment, on the other hand, is less satisfactory, and must be carried out each year to be effective Full working details, with costs, of the various methods are supplied and their relative merits discussed Attention is also directed to the fact that care is needed in the manurial treatment after steaming, for the soil tends to become specially rich in nitrogen and will require the addition of phosphate and potash only to secure a proper balance The use of stable manure may in such cases prove harmful The bulletin, No 22, which may be obtained direct from the Ministry of Agriculture 10 Whitehall Place, S W 1, price 1*s* post free, should prove of great value to all those interested in glasshouse crops, but growers are advised to consult an expert before undertaking sterilising operations for the first time

Raised Beaches of New Zealand —The recent disastrous earthquake in New Zealand lends additional interest to an investigation by L C King of the raised beaches of the south east coast of North Island (*Trans and Proc N Z Inst*, Vol 61, pp 498 523, 1930) It is shown that the coast line is one of emergence, except at Port Nicholson (a local downwarp) and Palliser Bay (a fault angle depression) Along most of the coast line studied, uplifted terraces of undoubted marine origin testify to the amount of comparatively recent uplift from place to place, and demonstrate that the movements were not uniform, but consisted of a series of interstage warpings and tiltings The two main terraces suggest a general axis of tilting somewhere in Cook Strait From Terawhiti to Black Rocks, the higher of these rises from 250 ft to 950 ft, and the lower from 125 ft to

700 ft The platforms are carved in hard greywacke A lower beach at 25 35 ft indicates that one of the latest movements of the coast appears to have been a general uplift of approximately 30 ft along almost the whole length described The paper is well illus trated and includes a useful critique for the discrimina tion between marine and alluvial terraces

Diffraction of Electrons in Gases - Many diffrac tion experiments have now been performed in which electrons or atoms are made to exhibit undulatory properties in interaction with periodic structures The *Proceedings of the Royal Society* for March con tains accounts of two sets of experiments which fur nish what is practically the electron analogy of the formation of haloes by clouds of fine particles of water, that is, diffraction by an obstacle the dimensions of which are comparable with the wave lengths of the electrons In the one case, studied by E C Bullard and H W Massey, the obstacles were the individual atoms in argon, in the gaseous phase, and in the other, studied by F L Arnot, atoms in mer cury vapour In both cases the apparatus was quite simple in principle, a beam of electrons was pro jected with definite speed into the gas or vapour at low pressure, and the electrons, which were scattered from a small volume into a Faraday cylinder without loss of energy, were measured for various orientations of the projecting and collecting systems The curves showing the variation of the current scattered, with angle of scattering, exhibit series of maxima and minima, which change in position as the energy, or wave length, of the electrons is changed The full theory of this type of scattering has not yet been developed, a fundamental difficulty occurring from the fact that the wave lengths of the electrons alter as they are accelerated or retarded in the fields of the scattering particles, but the qualitative course of the effect is what would be anticipated, and, in the case of argon, there is fair agreement between the results which have been obtained and those of Ramsauer for the effective cross section of the atom for slow electrons of various speeds

Gas Analysis Apparatus - The Bureau of Standards *Journal of Research* for January contains a paper by M Shepherd in which an improved volumetric apparatus is described for the analysis of gases by combustion and absorption methods, with details of manipulation The apparatus is of the Orsat type, that is, the series of pipettes is connected to the burette, but the adjustment and control of pressure balances have been greatly improved The combustion and absorption pipettes have been redesigned, and a new type of mounting permits the easy removal and replacement of any part It is suitable for rapid technical analysis Very complete details of construc tion and use are given

Chemistry of Disinfection — In a paper on the chemistry of disinfection, in the February number of the *Journal of Physical Chemistry*, W D Bancroft and G H Richter, from ultramicroscopical observa tions on the colloidal changes in living cells and bacteria, conclude that antisepsis in bacteria is merely a state of narcosis depending upon the reversible coagulation of the cell colloids Disinfection is brought about by the irreversible coagulation of the cell colloids The observations have shown that other means—action of heat, light, distilled water, or mechanical agitation—which produce coagulation also produce antisepsis or disinfection The mechanism of disinfection consists of two phases (1) the adsorption of the drug and (2) coagulation of the cell colloids, and the phenomena of stimulation are associated with the decreasing stability of the cell colloids in the initial stages of coagulation Drug tolerance is similarly attributed to fractional coagulation, with adsorption of the drug by the coagulum and simultaneous in creased stability owing to dilution of the sol Anti septics and disinfectants, like narcotics, can thus act in two ways, either directly coagulating the colloids, as in the case of phenol, or by interference with the normal cell functions so that accumulated toxic pro ducts produce the coagulation Arsenic derivatives appear to act in the latter indirect way

Diphenyl and its Derivatives —The *Journal of the American Chemical Society* for January contains a paper by Clark and Pickett on the X ray investigation of diphenyl and some of its active and inactive de rivatives It is known that substitution of certain groups in the 2, 2′, 6, 6′ positions in diphenyl gives rise to compounds which may be resolved into stereo isomers, and it is thought that the presence of suffi ciently large groups prevents the free rotation of the two rings and hence two active forms of such a com pound exist The examination of such compounds by X-rays should throw much light on their structure So far as the investigations have gone—and it is em phasised that accurate measurements of intensities are still required before certainty can be reached— they indicate that the two benzene rings in diphenyl are in prolongation of each other rather than doubled over each other, and this is also the configuration accepted by most organic chemists The rings are probably puckered, not flat, a conclusion also reached by Hengstenberg and Mark The width of the molecule is probably 5 6, the actual thickness less than 4 1, and the length greater than 9 5 The carb oxyl groups in diphenic acid probably exert forces upon each other which result in a doubling up of the molecule, a supposition which is in agreement with the ease of formation of an anhydride of this acid The thickness of the molecule is constantly 4 3 for the derivatives of diphenyl The width is 7 9 for hexachlorodiphenyl, and the length 10 75 The values for dimesityl and its diamino derivative indi cate a tilt of the rings

Barley Proteins - A contribution to this subject from the Tuborg Laboratories, Copenhagen, by G Hofman Bang appears in the February issue of the *Journal* of the Institute of Brewing (37, 72, 1931) It was found that the proportion of insoluble proteins (glutelin) varies according to the variety of barley, but that, for one particular variety, it is constant and independent of the soil conditions The salt soluble proteins decrease and the alcohol soluble proteins (hordein) increase with increase in the total protein content of the barley, though after drying there is an increase of both hordein and salt soluble proteins and a decrease in glutelin A conversion of salt-soluble protein into glutelin occurs, without, however, a change in hordein content, on storage of the barley At 20° C with samples containing 11 per cent or less of moisture this change is very slight, but the rate of reaction increases with increase of either temperature or moisture content These results are of consider able importance in their relation to the changes under gone by barley during malting, but they are also of great interest in that they substantially confirm, for Danish barleys, the relationships between the in dividual proteins already established by Bishop in Great Britain Some work has also been carried out on the influence of various practical malting con ditions on these relationships, and it has been shown that in the presence of large proportions of carbon dioxide germ-growth is checked and an accumulation of salt-soluble proteins in the malt is promoted

Pyrethrum as an Insecticide and its Cultivation in England

By J C F FRYER and C T GIMINGHAM, Plant Pathological Laboratory, Ministry of Agriculture

THE insecticidal properties of the flowers of certain species of pyrethrum (*Chrysanthemum*) have been known for a long period, the very high toxicity of the active principles to insects and their harmlessness to man and warm blooded animals forming an almost unique combination of qualities It is, however, within the last decade only that the chief advances towards a detailed knowledge of these plants have been made, and the marked interest aroused in the subject recently makes it appropriate to direct attention to the present position of investigations undertaken in Great Britain

Three species of pyrethrum, *Chrysanthemum cinerariæfolium* Trev, *C coccineum* Willd, and *C marschalli* Ascher (*roseum* Bieb), possess insecticidal properties Of these, the first named is much the most important, its flowers constitute the great bulk of the pyrethrum of commerce, and the work to be referred to has been confined almost exclusively to this species The plant is a native of the Mediterranean coast region, and is widely cultivated there and in Japan *, it is now also grown commercially for home consumption in Switzerland, France, and North Africa

Experiments on the cultivation of pyrethrum in England were started in 1925 by the Plant Pathological Laboratory of the Ministry of Agriculture,[1] small plots being laid down at some sixteen centres on a variety of different types of soil In co operation with the Insecticides and Fungicides Department of Rothamsted Experimental Station, samples of the produce from many of these plots during the years 1926–29 were tested by a biological method and later examined chemically (see below), and, without going into details, it may be said that the result of these experiments has demonstrated that pyrethrum can be grown and harvested successfully under English conditions, that the average yield of dried flowers is of the same order as that obtained elsewhere, and that the insecticidal efficiency of the product is not less than that of imported samples[2] The plants proved quite hardy and successfully withstood the fairly severe winters of 1927–29, a plot at Harpenden, planted in 1926, is still in good condition and gave its highest yield of flowers in 1930 These experiments, however, were on too small a scale to give data on which an opinion could be formed as to the economic possibilities of growing pyrethrum in England, and arrangements were therefore made to plant up several larger areas of ¼ to 1 acre, for which detailed costings could be kept Four of these bigger plots yielded their first harvest of flowers in 1930, and another should come into bearing this year It will be necessary to continue these investigations for several years before the desired information is obtained, but the first year's figures are, on the whole, not discouraging, though in one case the grower considered the crop too troublesome and has decided to discontinue the experiment The produce from all four plots was of high quality, two gave a yield which is about the average for a first year crop, the yield from the third was rather below the average, and from the fourth was very much higher Costs of planting and cultivation are much greater in the first year than later, but reckoning the produce at the current price of imported flowers (at present rather low), expenses were about covered in the case of the fourth plot These plots should continue to crop for at least another four years, during which the expenses of cultivation will be greatly reduced Thus, although the results so far obtained do not warrant confidence as to ultimate success, they certainly justify the continuation of the experiments Cutting the flowers by hand is probably the most serious item of expense, and labour costs will be considerably reduced if a mechanical means of harvesting can be devised

Laboratory investigations have proceeded concurrently with the field experiments The brilliant investigations of Staudinger and Ruzicka[3] elucidated the composition of the active principles of pyrethrum and showed that these were two esters of complicated structure, to which the names pyrethrin I and pyrethrin II were given A method for the determination of these substances was also suggested by Staudinger and Harder[4] Following up these researches, analytical methods, involving the use of only small amounts of material, were worked out at Rothamsted, and a number of samples were examined both biologically and chemically A close correlation was found between the percentage of pyrethrins in a series of samples and the observed insecticidal efficiency under standard conditions[5]

Another point to which special attention has been given is the relationship between the stage of development of the flower and the pyrethrin content It is an established convention in the trade that pyrethrum flowers picked before they are fully open ('half opened') possess greater insecticidal value than the fully opened flowers, and higher prices are given for the former † Biological experiments carried out under standard conditions have, however shown that the toxicities of extracts of equal weights of pyrethrum flowers at different stages of development do not differ significantly,[2] and a detailed investigation by Dr F Tattersfield (not yet published) of the pyrethrin content of flowers taken week by week over the flowering period, in which the large mass of data obtained is dealt with statistically, shows that the percentage of pyrethrins present increases up to the stage at which the flowers are fully open Gnadinger and Corl,[6] in America, using a different analytical method, have also found that the pyrethrin content of the flowers increases with maturity The point is of great practical importance, since the yield both of flowers and of active principles which can be harvested per unit area increases markedly with increasing maturity of the flowers

Evidence has accumulated in the past two years that many samples of pyrethrum grown in England contain a higher percentage of pyrethrins than is generally found in imported consignments Figures of 1 5–2 0 per cent are not uncommon, whereas imported samples commonly contain not more than 0 5 per cent Further, analysis of the flowers of individual plants have shown wide variations in pyrethrin content, and the possibility of evolving improved strains is under consideration

Pyrethrum insecticides were formerly confined very largely to powders obtained by grinding the dried flowers, but in recent years preparations for use as horticultural spray fluids have been on the market in America, and kerosene extracts of the flowers have been widely sold as fly sprays As was pointed out by Staudinger and Ruzicka, the pyrethrins undergo hydrolysis with alkalis, and

* Japan now provides about 70 per cent of the world's supply of pyrethrum For details of the history and present position of pyrethrum growing in Japan and the methods of cultivation adopted, see an article by the British Vice-Consul at Seoul in *Bull. Imp Inst*, Oct 1930, p. 300

† This opinion had been challenged by Swiss, French, and American workers many years ago, but without affecting the custom of the trade

preparations containing soap, such as the French 'savon pyrethre', are liable to gradual deterioration, petroleum extracts with a non alkaline emulsifier are however, stable for considerable periods A formula for the preparation of a spray fluid of the latter type has been published by Tutin,[7] and proprietary products of a similar kind were placed on the English market last year

Walton [8] has obtained very promising results with sprays of this type for the control of the raspberry beetle, a serious pest of raspberries and loganberries, and preliminary experiments with these fluids against red spider and against the apple capsid bug, both important pests of fruit and difficult to control, have also been successful Although different kinds of insects vary somewhat in the degree of resistance that they offer to the effects of pyrethrum, a great many important pests are killed by preparations containing 0 0025 to 0 005 per cent of pyrethrins, that is, approximately the equivalent of 0 5 to 1 0 per cent of flowers The pyrethrins appear to act upon insects as nerve poisons, and they are undoubtedly among the most powerful insecticides known, the range of their usefulness has by no means yet been fully explored

Geology in Great Britain

THE "Summary of Progress" of the Geological Survey of Great Britain for 1929 is issued in three parts, of which the first is devoted to an account of the routine work during the year under review, while the others contain papers on subjects of special interest Part 1[1] embodies the annual reports of the Geological Survey Board and of the Director Sixty six maps were published during 1929, with eight memoirs which, with the exception of that dealing with Moreton in Marsh (see below), have already been noticed in our columns (NATURE, Aug 16 1930, p 258) The memoirs in the press at the close of the year have since appeared and are reviewed below

The most important event in the progress of the Survey during 1929 was the beginning of operations for the building of a new museum, library, and offices on a site in Exhibition Road South Kensington, midway between the Natural History Museum and the Science Museum The Geological Museum will have direct connexion with each of these by means of passages open to the public The work now in progress will take at least three years to complete New offices have been occupied in Edinburgh and a scheme for the erection of an additional building is under consideration Field work has for some years been concentrated on the revision of the coalfields In Yorkshire Lancashire, and Northumberland this is still actively in progress, elsewhere the surveys are approaching completion, though the maps and memoirs have still to be published Reports on six districts in England and four in Scotland, and on the palæontological, petrological, and chemical work in progress, contain many records of current interest

In Part 2[2] the results of a magnetic survey of part of north Leicestershire are recorded and discussed by A F Hallimond A valuable petrological study of the hornfelses from Kenidjack, Cornwall, is provided by C E Tilley and Sir John Flett It is thought that the original dolerite intrusions of the area were intensely weathered and leached, and afterwards sheared and thermally metamorphosed with the production of cordierite anthophyllite rocks and cummingtonite rocks In view of the occurrence of similar rocks elsewhere in puzzling circumstances, this paper is of much more than local importance H G Dines and F H Edmunds show conclusively that it is unsafe to base stratigraphical deductions on mechanical analyses of the formations of the Lower Greensand Four other papers record noteworthy stratigraphical and palæontological observations

Part 3[3] contains an account of magnetic work on the Swynnerton Dyke, also by A F Hallimond Sir John Flett describes a teschenite, 224 feet thick, encountered in a boring at Easter Dalmeny, west of Edinburgh, and devotes special attention to the variation of mineral composition and specific gravity with depth The discussion of differentiation is particularly illuminating and should be seen by all petrologists Bernard Smith contributes a useful study of the origin of the St Bees Whitehaven Gap Important palæontological investigations are recorded in R Crookall's account of *Palæoxyris* and related genera, and in W S Bisat's paper on the goniatite and nautiloid fauna of the Middle Coal Measures of England and Wales The accurate determination of hitherto confused species makes possible a notable advance in the correlation of the English and German Coal Measures Other papers deal with the Pliocene of Hertfordshire and a boring in the Lower Oil shale Group of Burntisland

Few memoirs in recent years have approached that dealing with north Ayrshire,[4] in the wide variety, general interest, and scientific importance of the topics discussed The area is characteristic of much of the Central Valley of Scotland, and includes a long succession of sediments from the Downtonian to the New Red Sandstone, and a remarkable number of igneous episodes of different ages Lava suites occur in the Lower Old Red Sandstone, Calciferous Sandstone, Millstone Grit, and New Red Sandstone (? Permian) In addition, beds of volcanic ash occur at intervals in the Limestone Coal and Upper Limestone Groups, and there are many north west dykes that can confidently be referred to the Tertiary A remarkable range of petrographic types is represented, and petrologists abroad, as well as at home, will find the memoir a rich storehouse of highly significant records, analyses, and associations A summary of the geology and an account of previous researches are given in the first two chapters The chief rock groups, sedimentary and igneous, are ably dealt with in successive chapters Special attention is directed to the fauna of the Carboniferous and the flora of the Coal Measures A detailed account of the glaciation of the district follows and includes a description of fossiliferous beds of Pleistocene age found beneath the boulder clay of certain areas A special feature of the memoir is the chapter on the soils and agriculture of north Ayrshire It should be noted that in addition to the beautiful one-inch maps (Solid and Drift editions) published in 1928, a soil texture map on the same scale is also available The latter was issued in 1929 and was prepared under the supervision of the late Prof R A Berry

The new memoir on the Alnwick district[5] deals with the country stretching from the Cheviot foothills to the coast between Warkworth and Embleton, and includes some of the chief beauty spots of North-

umberland The rocks are mostly of Lower Carboniferous age and the diversity of sediments affords many interesting problems Of special interest is the famous Shilbottle coal, the most valuable Lower Carboniferous seam in the north of England Chapters are devoted to the Whin Sill, glacial, and post glacial deposits, and economic geology Details of borings and sinkings made in recent years are given in an appendix, and there is a useful glossary of the local and mining terms of north Northumberland

The Maryport memoir[6] covers part of the West Cumberland coalfield and is the first systematic account of a difficult and intricate region Most attention is given to the Productive Coal Measures their correlation with the seams in other parts of the field, the complicated faulting of the strata, and the structural features of the adjoining concealed coal field The whole district has been heavily glaciated, exposures are few, and detailed mapping has been largely dependent on mining information The remaining chapters deal with the Skiddaw Slates the Carboniferous Limestone the Whitehaven Sandstone series, the New Red Sandstone, glacial and recent deposits, and the economic geology of the district

The memoir[7] describing Sheet 77 deals with a region of great industrial importance, extending from Blackstone Edge Moors to Dewsbury, and embracing Huddersfield, Halifax, Batley, Brighouse, the southern part of Bradford, and some of the suburbs of Leeds The region lies on the easterly dip slopes of the Pennines, and, apart from the superficial deposits, the rocks all belong to the Millstone Grits and the Lower and Middle Coal Measures The geology of these formations is fully discussed, and there are chapters on structure, glacial deposits, local fossils, and economic geology, special attention being devoted to the goniatite zones and to the occurrence of marine bands in the coal measures Records of borings, a list of quarries, and a list of geological photographs (of which prints and lantern slides can be supplied) are given as appendices

The district represented on Sheet 217 is an attractive residential and agricultural area in the Cotteswolds ranging from Cheltenham to Chipping Campden[8] Roughly, about half the region is in the Severn basin and about half in the Thames basin Apart from the superficial formations, which are here of great variety and interest, and the concealed Palæozoic floor, the rocks belong to the Lower and Middle Jurassic Since the days of Murchison (who described the geology in 1834) the area has provided an attractive field for many active workers, including the late S S Buckman and the author of the memoir Mr Richardson has demonstrated, for the first time, the relationships of the Estuarine deposits of southern Northamptonshire and northern Oxfordshire to the marine Inferior Oolite of the Cotteswolds The memoir is an admirable guide to the geology of a classical and much visited region

The next two memoirs belong to the county series in which the sources of underground water are recorded The Worcestershire volume[9] provides an excellent short account of the geology and structure of the county, and is illustrated with a clear map and several sections The chief regional water undertakings are covered, and the supplies of the rural and urban areas are described in detail Special attention is given to the waters of Malvern and Droitwich, and a comprehensive series of water analyses is provided by the county analyst, Mr C C Duncan The Gloucestershire memoir[10] is of unusual interest because of the great variety of rocks that occur in this variegated and delightful county As usual in this series, an admirable general introduction to the geology is provided, with maps and sections Detailed accounts of the water supplies of Bristol, Gloucester, and Cheltenham are given The saline waters of Cheltenham originate in the Lower Lias, while the chalybeate springs issue from a superficial gravel in which there is an admixture of peaty matter Other rural and urban district supplies are described with a wealth of detail, and numerous analyses and full bibliographies are added Twenty four memoirs on the underground water supplies of counties have been published to date

(London H M Stationery Office)

University and Educational Intelligence

Aberdeen —The honorary degree of LL D was conferred upon the following among others, at the graduation held on April 1 Sir Leonard Hill, Sir Frank Smith, Prof C R Marshall, and Sir J Arthur Thomson

Cambridge —The Appointments Committee of the Faculty of Economics and Politics will shortly proceed to appoint a University lecturer in statistics, the duties to begin on Oct 1 Candidates are requested to communicate with the Registrary of the University not later than May 1

The General Board has made the following grants from the Worts Fund £100 to the Zoological Station at Naples, £45 to Miss W Lamb, of Newnham College, for the continuation of her excavations at Thermi, £45 to Dr E B Worthington, of Gonville and Caius College, towards the expenses of the Cambridge Expedition to the East African Lakes, £45 to Dr L S B Leakey of St John's College, for archæological, palæontological, and geological investigations in East Africa, £45 to G Bateson, of St John's College, for anthropological work in New Guinea, £30 to R T Wade, of Clare College, towards his expenses in connexion with visits to museums in Europe to study fossil fish, £20 to P W Richards, of Trinity College, towards the expenses of a botanical expedition to the Sierra Nevada, £15 to T H Cox, of Magdalene College, for geological exploration in Baffin Land

It is proposed to confer the degree of Sc D *honoris causa* upon Prof J S Haldane, honorary professor and director of the Mining Research Laboratory in the University of Birmingham

Edinburgh —At the meeting of the University Court on Mar 23, a letter was read from Sir Alexander

Rodger, formerly Inspector-General of Forests, India, intimating that he desired to present a prize for the best student in forestry graduating in 1931, 1932, and 1933 The Court gratefully accepted this gift

The intimation of a gift to the University from an anonymous donor of £5000 towards the cost of furnishing the new Masson Hall, directs attention to a movement that is on foot to remove the present hall from George Square to a new site at West Mains Road, where it will be capable of accommodating about one hundred resident students in addition to the staff Plans have been prepared and the building will be proceeded with as soon as the necessary funds are available The estimated cost of the new building is £50,000

Prof James C Brash has been appointed by the curators to the chair of anatomy in the University, to succeed Prof Arthur Robinson, who is resigning at the end of the current academic year

LONDON —Miss G K Stanley has been appointed, as from Aug 1, to the university readership in mathematics tenable at Westfield College

It has been resolved to institute a university chair of experimental pathology tenable at the Cancer Hospital (Free)

The Petrie Medal for distinguished work in archæology has been awarded to Sir Arthur Evans

APPLICATIONS for Beit junior memorial fellowships for medical research can now be received They should be sent at latest during May to Prof T R Elliott, Beit Memorial Fellowships for Medical Research, University College Hospital Medical School, University Street, W C 1

A SPECIAL course of seven lectures on "Internal Combustion Engines and Lubrication" will be given by different specialists at the Sir John Cass Technical Institute, Jewry Street, Aldgate, London, E C 3, on Mondays and Thursdays from April 13 to May 4 The course has been specially arranged for those engaged in the technical branches of the petroleum industry

A LIMITED number of agricultural scholarships for students who propose to take up posts as agricultural organisers, teachers or lecturers in agriculture, etc, are being offered by the Ministry of Agriculture and Fisheries Form No A 472/T G and particulars can be had from the Secretary of the Ministry, 10 Whitehall Place, S W 1 Completed forms are returnable by, at latest, June 15 The Ministry also invites applications for some research scholarships in agriculture and veterinary science Applications must be received not later than June 15 on Form 900/T G, which, with a copy of the conditions attached to the scholarships, may be obtained from the Secretary of the Ministry

NOTICE is given by the Institution of Electrical Engineers that the triennial award of the Coopers Hill War Memorial prize and medal will this year be made for a paper on one or other of the following subjects —The use of electricity in public works, hydro electric power developments, electrification of railways, electricity in agriculture, electricity in mines, long distance telephony (excluding wireless), long distance telegraphy (excluding wireless), overhead lines in rural districts, extra high voltage underground cables and their protection, Empire wireless communications The competing essays, which must be written specially for the occasion, must reach the Secretary of the Institution of Electrical Engineers, Savoy Place, W C 2, by Oct 1 next at latest

Birthdays and Research Centres.

April 14, 1867 —Prof J C McLENNAN, F R S., professor of physics and director of the Physical Laboratory, University of Toronto

In collaboration with one group of associates, I am determining the spin moments of the nuclei of several types of atoms with the object of gaining information of a definite character regarding the structure of such nuclei With another group, studies are being made of the optical and electrical properties of metals at the lowest temperatures with the object of elucidating the phenomenon of superconductivity With a third group, problems in spectroscopy are under investigation, involving not only gases but also solids and liquids I am also directing a special investigation on the heating effects produced by very short radio waves, another on the products obtainable with mixtures of certain gases subjected to irradiation by high speed electrons, and still another on auroral phenomena

April 17, 1863 —Prof GEORGE GRANT MACCURDY, curator of the anthropological collection at Yale University and director of the American School of Prehistoric Research

I am at present engaged on (1) a small volume to be called "The Coming of Man", (2) Director's Report, *Bulletin* No 7, the American School of Prehistoric Research, for 1930, (3) article on archæology and prehistory for a new encyclopædia

Societies and Academies

LONDON

Optical Society, Feb 12 —T Smith Modern optical glass as exemplified by the list of the Parsons Optical Glass Co, dated September 1926 The optical positions (μ ν) of the glass types catalogued by the Parsons Optical Glass Company and the relations between the dispersions for several segments of the visible spectrum are exhibited graphically A knowledge of the refractive indices of any glass for three wave lengths is sufficient to specify the index for the whole of the visible spectrum, and a knowledge of two indices is almost sufficient In particular, the partial dispersive ratios are almost functions (nearly linear functions) of ν only This implies that there are no glasses suitable for making apochromatic telescope objectives of large relative aperture The graphs show that the general standard of accuracy of the measured indices is high A new graphical method of interpolating refractive indices for glass is obtained —J Guild On the fixed points of a colorimetric system. The paper discusses the significance of the constants which enter into the specification of colour on the trichromatic system, and suggests certain fundamental considerations of a metrological character which ought to govern the choice of such constants in a standard reference system Various proposals which have been put forward from time to time are discussed in the light of these considerations, and the basis of the system which has been adopted at the National Physical Laboratory is explained

Royal Meteorological Society, Feb 18 —L J Sutton Note on haboobs This note is a revision and extension of a paper which appeared in the Society's *Journal* in 1925 on the severe dust storms which occur in the north and central Sudan, chiefly during the rainy seasons The statistics, which are drawn mainly from the records of Khartoum, include

frequency of occurrence, direction, diurnal variation, and average velocity Most of the haboobs appear to be due to a current of relatively cold air undercutting warm air, probably in many cases connected with the diurnal variation of temperature, which in the summer causes a depression to form during the day time over the hot arid region between Khartoum and the Nubian Desert —**S Chapman** and **Miss M Hardman** The lunar atmospheric tide at Ocean Island The lunar atmospheric tide at Ocean Island, in the Pacific, has been determined from hourly data extending, with gaps, from 1904 to 1912, or the equivalent of about five years' continuous data The annual mean semiamplitude of the tide is found to be 71 microbars, and maximum pressure occurs at about 20 minutes after lunar transit —**A C Best** Horizontal temperature differences over small distances The temperature differences over two intervals of 25 feet and 50 feet at a height of 4 feet above the ground were recorded for nearly three months It was found that during the daytime the air was not homogeneous The temperature fluctuated rapidly at any one spot, the amplitude being as much as 1 5° F under conditions of low wind velocity This non homogeneity decreased as the wind increased There is some evidence that the state of the sky also affects the amplitude of the temperature fluctuations At night the fluctuations became much slower and temperature differences up to 1 5° F persisted for periods up to 30 minutes, usually under conditions of low wind velocity The daytime periods and the night periods were usually connected by a short period of one or two hours, when the air at 4 feet was very homogeneous with regard to temperature —**E Ll Davies** A portable temperature gradient indicator The method consists essentially of measuring the differences in resistance of two platinum elements exposed at different heights above the ground The advantages and disadvantages of three types of housing for resistance elements are given in detail With the electrically aspirated housing a good galvanometer (sensitivity about 2 mm of scale per microampere), differences of temperature to within 0 1° F are measurable

Physical Society, Feb 20 — **G G Sherratt** and **J H Awberry** On the velocity of sound waves in a tube The apparent velocity of sound in a tube of diameter 2 cm has been measured at temperatures up to 400° C and with frequencies of from 3000 to 14,000 ~ The reduction in velocity below the free air value is discussed, and the suggestion is put forward that this reduction, for a single tube and gas, depends on the wave-length rather than on the frequency The theoretical expression found by Helmholtz and Kirchhoff for the reduction in velocity does not appear to be valid The method used by Dixon and by Partington and Shilling for correcting for the influence of the tube receives support —**P S H Henry** The tube effect in sound-velocity measurements The modifications in Kirchhoff's formula required to take account of the finite thermal conductivity of the tube, slip between the gas and the walls, temperature discontinuity between the gas and the walls, and absorption of energy by the walls are calculated and found to be negligible The effect of roughness of the walls is discussed, and the conclusion is drawn that the large tube-effects often found in practice are due to irregular motion of the gas —**W A Wood** A note on the elimination of the β wave length from the characteristic radiation of iron The method is based upon the selective absorption produced by a thin film of pure manganese which is obtained in the required form by electro deposition upon aluminium foil

Geological Society, Mar 4 —**W A Macfadyen** The geology of British Somaliland Some 100,000 square kilometres were mapped geologically for the first time, on the scale of 1 250,000 The larger part consists of a great plateau sloping very gently to the south-south east, fronted by a relatively low lying area of broken surface features and faulted strata Terrace gravels occur up to an altitude of 594 metres near Dagah Shabell, where they are best developed, and the river system of that district is a fine example of superimposed drainage Raised beaches are found in the Berbera district at levels of 8 metres, about 85 metres, and 200 metres, none is earlier than Pleistocene In the coast district particularly south of Bulhar and along the Jibuti border in the west, are basalts and lavas, with the dissected volcano of Elmis, all are probably of Pliocene age and later The fragmentary Dubar Series, approximately of Burdigalian age, is restricted to the coastal district The Daban Series, 2300 metres thick and resting conformably on the gypsum, occurs locally in the Guban country The south eastern half of the country is covered by Eocene strata Over the eastern part of the plateau outcrop the richly fossiliferous Middle Eocene limestones and marls 230 metres thick The Eocene rests on Cretaceous Nubian Sandstone, up to about 200 metres thick in parts of the Guban, where it includes the Shabell Beds, 830 metres of grits and red clays Jurassic strata in faulted outcrops occur only north of the plateau, except in the north east A measured section 910 metres thick, showing the complete developments near Bihendula, is found from the ammonite fauna to be mainly of Kimmeridgian age, only the uppermost 150 metres is later, while the basal 80 metres is earlier

Mineralogical Society, Mar 17 —**A J P Martin** On a new method of detecting pyro electricity On changing the temperature of certain crystals, electric poles of opposite sign are developed at the two ends In these experiments the temperature change is produced by cooling in liquid air and the electric charge is detected in the following way The crystal is suspended by a long thin glass fibre near to the copper plate, which may be moved near to, or away from, the crystal, both of them being immersed in the liquid air The charge on the crystal induces an equal and opposite charge on the plate, and the attraction between the two, causes the crystal to move nearer the plate This method is specially suited to very small crystals or to those which are decomposed on heating —**D R Grantham** and **F Oates** On the Mbosi meteoric iron, Tanganyika Territory A wedge shaped mass of meteoric iron measuring 10 ft × 4 ft × 3 ft and estimated to weigh 12 15 tons was found late in 1930 near Mbosi, between Lakes Tanganyika and Nyasa It is a medium octahedrite containing 8 69 per cent of nickel —**S R Nockolds** On the Dhoon (Isle of Man) granite a study of contamination The Dhoon granite forms a small boss-like mass intruded into the Lonan Flags Two main types are present, one of which is slightly earlier in date than the other The difference between the two types is mainly textural The main type may be termed biotite granodiorite porphyry, whilst the other is a biotite granodiorite Both types are abnormal in that the biotite occurs in clots and in association with zoisite, ilmenite (usually with a border of granular sphene), sphene itself, and, more rarely, epidote, clinozoisite, and garnet These clots represent the last remnants of a regionally metamorphosed basic igneous rock which has been absorbed by the original granitic magma It is concluded that the original magma was of alkali-granite type and similar to the

quartz porphyry dikes which are associated with the mass All the evidence points to an extensive inter change of oxides between the original magma and the basic igneous rock Further, it is shown that the peculiar albitisation of the felspars in the 'granite' of both types is indirectly dependent on the contamination —**A G MacGregor** On clouded felspars as a result of thermal metamorphism A special type of cloudiness in plagioclase due to the development of minute inclusions is shown to be the result of contact thermal metamorphism acting after con solidation of the igneous rock The effects have been observed in various contact metamorphosed lavas in Scotland Similar cloudiness is observed in the Scourie Dyke, the 'hyperites' of Sweden, malchite of Melibocus, and many other rocks The possibility of similar clouding being produced as a deuteric effect at a late stage in consolidation is considered —**C N Fenner** On the residual liquids of crystallising magmas Discussion of the character of the residues left by the crystallisation of magmas A short summary is given of outstanding points of evidence that should be taken into consideration in forming an opinion on the broad problems of differentiation

EDINBURGH

Royal Society, Feb 2 —**Sir E Sharpey Schafer** Observations on the relative rate growth of the nails of the right and left hands, on seasonal variations in the rate, and on the influence of cutaneous nerves upon it The rate of growth of the finger nails was faster in summer than in winter, and faster on the right hand than on the left A notable exception was presented by the thumb nails, which grew faster on the left hand than on the right, both in summer and winter The slowest rate of growth occurred in the nail of the little finger of the left side The cutaneous nerves of this finger had been severed and, with the exception of those which subserve pain, had not shown any functional recovery It is therefore possible that a trophic influence is exercised through the cutaneous nerves upon the growth of the nail, the possibility being supported by the fact that the little finger nail on the left or denervated side not only exhibited a slower rate of growth, but also is distinguished from the corresponding nail on the normal side in being more flattened in form, rougher on the surface, and more brittle in texture —**F J W Whipple** A note on the secular changes of rock temperature on the Calton Hill The temperature of the rock forming the Calton Hill at Edinburgh has been studied since 1837 The long series of observations was analysed recently by Mr R W Wrigley, who concluded that the fluctuations which he had discovered had their origin in the interior of the earth, and sought to correlate them with irregularities in the earth's rotation There are difficulties in accepting this interpretation of the observations It is maintained that the fluctuations of temperature are probably propagated downwards from the surface A possible explanation is that there was less sunshine at Edinburgh in the latter half of the nineteenth century than in recent years There are, however, no comparable sunshine records by which this hypothesis can be tested

PARIS

Academy of Sciences, Feb 23 —**Ch Fabry** and **H Buisson** The absorption of radiations in the lower atmosphere and the estimation of ozone From measurements of the optical density of the lower atmosphere the proportion of ozone by volume is deduced to be $2\ 2\times10^{-8}$ The higher atmosphere is much richer in ozone —**Louis Roy** The comparison of the effects of diffraction in reflecting and refracting telescopes —**V Lalan** Contribution to the study of the curve of pursuit —**Paul Delens** The congruences of curves —**Georges Giraud** Certain problems concerning systems of equations of the elliptic type —**Georges Durand** and **Gaston Rabaté** Two conceptions of the limit ensemble and an infinite collection of point ensembles —**Georges Valiron** Remarks on the theorem of Borel in the theory of meromorph functions —**J Haag** The realisation of mechanisms of pure rolling Remarks on a recent paper by F E Myard —**d'Ocagne** Remarks on the preceding paper —**R Tremblot** The study of gaseous currents by means of interference —**Ch Volet** The application of the method of least squares to the calculation of the orbits of double stars —**L Dubar** The influence of the thermal treatment on the characteristics of copper oxide rectifiers When the current is in the direction copper to oxide, it is little affected by thermal treatment, but in the reverse direction, oxide to copper, thermal treatment produces large variations in the current In the case given, the current can be varied from 0 05 ampere to 10 amperes under the same voltage, according to the thermal treatment —**P Fourmarier** The existence of an abnormal magnetic flux Critical discussion of the views of W Mitkevich the author considers that the experiments of Mitkevich are insufficient to establish the existence of a normal magnetic flux —**R de Mallemann** and **P Gabiano** The variation of the specific magnetic rotatory power in the passage from the liquid state to the gaseous state The variation of the magnetic rotatory power in the change of state may be calculated with a good approximation starting from the factor $\phi(n)=\left(\frac{n^2+2}{3}\right)$ of Lorentz any other factor, such as that of Gladstone, is markedly out of agreement with experiment —**G Bruhat** The absorption of aqueous solutions of tartaric acid The author's experimental results, and the later figures of Lucas and Schwob, are in contradiction with the classical hypothesis of the existence in solutions of two different forms of tartaric acid —**G Reboul** and **J Sambussy** The passage of the continuous (electric) current in acetone A description of experiments carried out with the view of finding out the cause of the contradictory results obtained by H Garrigue and by P Lafond The difference was traced to the effect of light on the acetone —**M Battegay** and **L Denivelle** The aryl chlorosulphinates and the aryl sulphites By the interaction of sodium phenate and thionyl chloride, in addition to phenyl sulphite, the chloride C_6H_5 O SOCl has been isolated —**Paul Lemoine** The geological and hydrogeological results of a boring at the National Natural History Museum —**Jean Lacoste** Tectonic observations on the southern Riff (Moulay Bou Chta region) —**Mme Mara Lechtova-Trnka** The presence of an ascomycete in a tubercle of *Astragalus alopecuroides* The name *Ascorhiza Leguminosarum* is suggested for this mould, which appears to be new It has been found in the tubercles of three other Leguminosæ —**Pierre Dangeard** The sensibility of *Laminaria* to external actions and iodovolatilisation —**G Nicolas** and **Mlle Aggéry** A new example of the important rôle of bacteria in phytopathology —**Emile Saillard** The fixity of composition of plants, according to Liebig, and the sugar beet produced by selection The quantity of mineral bases contained in the entire plant per 100 kgm of sugar in the root, or per 100 kgm of dry material, is not constant, it diminishes as the richness of the roots in sugar increases The sugar beet, produced by selection, has not the fixity of composition indicated by Liebig —**Jean Roy** The existence of parthenogenesis in a species of Copepod

Elaphoidella bidens —**Georges Morin and Jean Boucomont** Modifications of chronaxy in experimental rickets of the rat —**Louis Lapicque** Remarks on the preceding communication —**G Ramon, R Legroux, and M Schoen** The dissociation of the diphtheric anatoxin antitoxin complex and the recuperation of the anatoxin —**A Demolon and G Barbier** Fermentations in a heterogeneous and discontinuous medium The medium was brick clay or a quartz sand moistened with a suitable nutritive liquid, the organisms, yeast, *B coli*, and a mobile urobacillus The phenomena of diffusion and migration take place in quartz sand when there is 6-8 per cent of water present, but this is not the case with a siliceous clay medium —**H Jacotot** Researches on vaccination against bovine plague the preparation of the antigen by dehydration of the virulent splenic pulp

Diary of Societies

FRIDAY APRIL 10

ROYAL ASTRONOMICAL SOCIETY at 5 —L H Thomas A Criticism of Current Theories of Stellar Structure and a Suggestion —H Roth The Density Distribution in Capella —Dr H Jeffreys On the Cause of Oscillatory Movement in Seismograms —S F Grace Tidal Oscillations in Rotating Rectangular Basins of Uniform Depth —G Shajn On the Behaviour of Certain Simple Multiplets in Stellar Spectra

MALACOLOGICAL SOCIETY OF LONDON (at Linnean Society), at 6 Exhibits, including *Opisthoporus* and *Lymnaea stagnalis* (L).

SOCIETY OF CHEMICAL INDUSTRY (Manchester Section) (Annual General Meeting) (at Engineers Club, Manchester) at 7 Dr A E Dunstan The Present Position of the Thermal Decomposition of the Lower Hydrocarbons

INSTITUTION OF MECHANICAL ENGINEERS (Informal Meeting) at 7 —H Roe and others Discussion on Aerial Ropeways

OIL AND COLOUR CHEMISTS ASSOCIATION (Manchester Section) (at Milton Hall, Manchester) at 7 —Annual Meeting

SOCIETY OF CHEMICAL INDUSTRY (South Wales Section) (Annual General Meeting) (at Mayfair Cafe Cardiff), at 7 15 —Prof W J Jones Chairman s Address

JUNIOR INSTITUTION OF ENGINEERS at 7 30 —F Russell Difficulties in Power Transmission by Belt and how to overcome them

SATURDAY, APRIL 11

GILBERT WHITE FELLOWSHIP (Annual General Meeting) (at 6 Queen Square W C 1) at 2 30 —Sir Richard Gregory Bart. Comets and Shooting Stars (Lecture).

MONDAY, APRIL 13

VICTORIA INSTITUTE (at Central Buildings, Westminster), at 4 30 —Rev Dr D M McIntyre The Jewish Apocalyptic and its Bearing on the New Testament.

ROYAL GEOGRAPHICAL SOCIETY at 5 —P Lake Island Arcs and Mountain Building

INSTITUTE OF TRANSPORT (at Institution of Electrical Engineers) at 5 30 —Debate The Final Report of the Royal Commission on Transport.

INSTITUTION OF ELECTRICAL ENGINEERS (Mersey and North Wales (Liverpool) Centre) (at Liverpool University) at 7 Annual General Meeting

INSTITUTION OF ELECTRICAL ENGINEERS (North Eastern Centre) (at Armstrong College, Newcastle upon Tyne), at 7 —Annual General Meeting

CERAMIC SOCIETY (Pottery Section) (at North Staffordshire Technical College, Stoke on Trent) at 7 30 —W Podmore Pottery Engineering —its Failures and Possible Improvements —A S W Odelberg The Durability of Bone China Hotel Ware

ROYAL INSTITUTE OF BRITISH ARCHITECTS, at 8 —G Grey Modern Flats

ROYAL SOCIETY OF ARTS, at 8 —Dr N A V Piercy The Present Position in Aeronautics (Howard Lectures) (1).

SOCIETY OF CHEMICAL INDUSTRY (London Section) (at Chemical Society), at 8.—J W Walters Studies in the Free Air Cooling of Hot Gases in Mains —F L Bassett Some Factors affecting the Corrosion of Buried Steel

INSTITUTION OF ELECTRICAL ENGINEERS (South Midland Centre) (at Birmingham University)—Annual General Meeting.
INSTITUTION OF ELECTRICAL ENGINEERS (Western Centre) (at Cheltenham).—H. T. Young: Modern Lighting (Lecture).

TUESDAY, APRIL 14.

ROYAL SOCIETY OF MEDICINE (Orthopædics Section), at 5.30.
ZOOLOGICAL SOCIETY OF LONDON, at 5.30.—Dr. W. E. Le Gros Clark: The Brain of *Microcebus murinus*.—M. Burton: The Interpretation of the Embryonic and Post-larval Characters of certain Tetraxonid Sponges, with Observations on Post-larval Growth stages in some Species.—Dr. R. Bigalke: Note on the Egg of the Nile Crocodile (*Crocodylus niloticus*).—D. L. Bryce: Report on the Rotifera. Mr. Omer Cooper's Investigations of the Abyssinian Freshwaters (Dr. Hugh Scott Expedition).—I. Filipjev: Report on Freshwater Nematoda. Mr. Omer Cooper's Investigation of the Abyssinian Freshwaters (Hugh Scott Expedition).—Col. A. E. Hamerton: Report on the Deaths occurring in the Society's Gardens during the Year 1930.
INSTITUTION OF CIVIL ENGINEERS, at 6.—R. W. Mountain: The 132 Kilovolt Transmission System of the Central Scotland Electricity Scheme.—C. S. Berry, H. P. Gaze, and C. E. H. Verity: The Deptford West Power Station of the London Power Company, Limited.
INSTITUTE OF MARINE ENGINEERS, at 6.—F. A. Pudney: The Caprotti Bauer Wach Marine Installation.
INSTITUTION OF ELECTRICAL ENGINEERS (London Students Section), at 6.15.—L. S. Crutch: Long Distance Telephony To-day.
SOCIETY OF CHEMICAL INDUSTRY (Birmingham and Midland Section) (Annual Meeting) (at Chamber of Commerce, Birmingham), at 6.30.—At 7.—F. R. O'Shaughnessy: Some Modern Methods of Sewage Disposal.—Dr. H. E. Lockwood and Dr. R. S. Hayes: A New Method of Testing Agar and Gelatine Jellies.
INSTITUTION OF ELECTRICAL ENGINEERS (North Midland Centre) (at Hotel Metropole, Leeds), at 7.—Annual General Meeting.
INSTITUTION OF ELECTRICAL ENGINEERS (Scottish Centre) (at 39 Elmbank Crescent, Glasgow) (Annual General Meeting), at 7.30.—B. Leggott: The Medical and Surgical Applications of Electricity.
QUEKETT MICROSCOPICAL CLUB (at 11 Chandos Street, W.1), at 7.30.—W. E. Watson Baker and others: Discussion on Microscope Design with special reference to Advances since 1914.
INSTITUTION OF ENGINEERS AND SHIPBUILDERS IN SCOTLAND (at 39 Elmbank Crescent, Glasgow), at 7.30.—Dr. L. A. Willcox and J. D. Farmer: A Comparison of Refrigeration Systems.

WEDNESDAY, APRIL 15.

ROYAL SOCIETY OF MEDICINE (History of Medicine Section), at 5.—Dr. J. D. Rolleston: J. B. Bouillaud (1796–1881), a Pioneer in Cardiology and Neurology.
ROYAL METEOROLOGICAL SOCIETY, at 5.—W. D. Flower: An Analysis of the Cold Front over Egypt on Mar. 7, 1929.—W. H. Pick: A Note on the Relationship between Fog and Relative Humidity.—H. Jameson: Temperature Observations on Adam's Peak, Ceylon.—*To be taken as read*.—S. P. Wiltshire: The Correlation of Weather Conditions with Outbreaks of Potato Blight.
ROYAL MICROSCOPICAL SOCIETY (at B.M.A. House, Tavistock Square), at 5.30.—L. La Cour: Improvements in Everyday Technique in Plant Cytology.—Prof. A. G. Hornyold: On the Preparation of Eel Scales.
NEWCOMEN SOCIETY FOR THE STUDY OF THE HISTORY OF ENGINEERING AND TECHNOLOGY (at Prince Henry's Room, Fleet Street), at 5.30.—Col. R. E. B. Crompton: The First Installation of House to House Supply in the United Kingdom.—G. A. Orrok: The Pearl Street Station: The First Steam Power Station in America.—Prof. J. K. Finch: The Civil Engineering Achievements of John B. Jervis.
INSTITUTE OF FUEL (Annual General Meeting) (at Chemical Society), at 6.—A. Marsh: Smoke Problem: A Consideration of some of its Economic Aspects and the Difficulties of its Solution.
INSTITUTION OF CIVIL ENGINEERS (Students Meeting), at 6.30.—F. C. Ball: Some Considerations on the Economic Design of Small Reinforced Concrete Girder Bridges for Highway Use.
INSTITUTION OF ELECTRICAL ENGINEERS (Sheffield Sub-Centre) (at Royal Victoria Hotel, Sheffield), at 7.30.—D. B. Hoseason: The Cooling of Electrical Machines.
ROYAL SOCIETY OF ARTS, at 8.—D. R. Wilson: Industrial Lighting.
ELECTROPLATERS AND DEPOSITORS TECHNICAL SOCIETY (at Northampton Polytechnic Institute), at 8.15.—S. Wernick: Experiments in Cadmium Plating.
SOCIETY OF GLASS TECHNOLOGY (at Sheffield).—Annual General Meeting.

THURSDAY, APRIL 16.

INSTITUTION OF MINING AND METALLURGY (at Geological Society), at 5.30.
CHILD-STUDY ASSOCIATION (at 90 Buckingham Palace Road), at 6.—Dr. J. N. Glaister: Does the Developing Mind Recapitulate Ancestral History?
INSTITUTION OF ELECTRICAL ENGINEERS, at 6.—R. M. Charley: Recent Progress in Large Transformers.—W. E. M. Ayres: The Application of the Induction Voltage Regulator.
ROYAL AERONAUTICAL SOCIETY (at Royal Society of Arts), at 6.30.—Dr. A. H. Davis: Aircraft Noise.
INSTITUTION OF ELECTRICAL ENGINEERS (Irish Centre—Dublin) (at Trinity College, Dublin), at 7.45.
BRITISH INSTITUTE OF RADIOLOGY, at 8.30.—Dr. H. S. Souttar: The Ideal Distribution of Radon Seeds.—W. E. Schall: A Two Valve Transformer Unit for Diagnosis and Therapy.—Dr. A. Orliansky: Uniformly Impressed Reduced Prints from Contrasty Negatives.—Dr. L. A. Rowden: A Technique of Radiographic Pelvimetry.

FRIDAY, APRIL 17.

BRITISH INSTITUTE OF RADIOLOGY (at North Middlesex Hospital, Edmonton), at 11 A.M.—At 5.—Meeting of Medical Members.
ELECTRICAL ASSOCIATION FOR WOMEN (at Park Lane Hotel), at 11.30 A.M.—Annual General Meeting.—At 3.—Report from Branches, etc.

PHYSICAL SOCIETY (at Imperial College of Science and Technology), at 5.—A. J. Maddock: The Generation of Current Pulses of Rectangular Wave-form.—R. A. Fereday: An Improved Method for the Comparison of Small Magnetic Susceptibilities.—Dr. E. G. Richardson: Edge Tones.
NATIONAL INSTITUTE OF INDUSTRIAL PSYCHOLOGY (Annual General Meeting) (at Royal Society), at 5.
ROYAL SANITARY INSTITUTE (at Guildhall, Poole), at 5.—E. J. Goodacre and others: Discussion on Some Aspects of Municipal Sanitation.—Alderman J. C. Julyan and others: Discussion on Prospect and Retrospect.—Dr. G. Chesney and others: Discussion on Diphtheria Immunisation at Work.
INSTITUTION OF MECHANICAL ENGINEERS, at 6.—C. D. Gibb: Post-War Land Turbine Development.
NORTH EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (at Mining Institute, Newcastle-upon-Tyne), at 6.—J. Foster King: Corrosion of Oil Tankers.
COKE OVEN MANAGERS ASSOCIATION (Midland Section) (at Sheffield University), at 6.30.—Prof. R. V. Wheeler: Rational Analysis of Coal.
SOCIETY OF DYERS AND COLOURISTS (Manchester Section) (at 36 George Street, Manchester), at 7.—H. E. Potts: The Patent Law relative to the Chemist and Technologist.
INSTITUTION OF ELECTRICAL ENGINEERS (Meter and Instrument Section), at 7.—E. W. Hill and G. F. Shotter: Current Transformer Summations.
INSTITUTE OF FUEL (East Midlands Section) (at University College, Nottingham), at 7.—H. I. Lirie: Theory and Practice of the Gasification of Coal in Producers.
SOCIETY OF CHEMICAL INDUSTRY (Newcastle Section) (at Armstrong College, Newcastle-upon-Tyne), at 7.30.—Demonstration of Modern Scientific Instruments and Apparatus of Special Interest.
INSTITUTE OF METALS (Sheffield Section) (in Non-Ferrous Section of Applied Science Department, University of Sheffield), at 7.30.—R. Genders: Extrusion.
JUNIOR INSTITUTION OF ENGINEERS, at 7.30.—J. E. Gray: The Transmission of Gas.—T. G. Martin: The Building Requirements of Lifts.
INSTITUTE OF BREWING (Yorkshire and North Eastern Section) (at Queen's Hotel, Leeds).—Annual Meeting.

PUBLIC LECTURE

TUESDAY, APRIL 14.

GRESHAM COLLEGE, at 6.—Sir George Newman: Physic. (Succeeding Lectures on April 15, 16, and 17.)

DISCUSSION

APRIL 17 AND 18.

A GENERAL DISCUSSION ON PHOTOCHEMICAL PROCESSES.

FARADAY SOCIETY (in Department of Chemistry, Liverpool University).
Friday, April 17, at 10 A.M.—Molecular Spectra in Relation to Photochemical Change.
Introductory Paper: Prof. R. Mecke.
Ultra-violet Absorption Spectra of Acetylene and Formaldehyde: Dr. G. Herzberg.
The Absorption Spectra and the Optical Dissociation of the Hydrides of the Oxygen Group: C. F. Goodeve and N. O. Stein.
The Photochemical Properties of the Carbonyl Group: F. W. Kirkbride and R. G. W. Norrish.
Friday, April 17, at 2.30.—Photochemical Kinetics in Gaseous Systems.
Introductory Paper: Prof. M. Bodenstein.
The Reaction between H_2 and O_2 under the Influence of Photochemically produced H Atoms. The Relation of its Mechanism with that of the Explosive Gas Reaction at High Temperatures: Dr. W. Frankenburger.
The Photochemical Union of Hydrogen and Chlorine at Low Pressures: J. B. Bateman and H. C. Craggs.
The Photosensitised Decomposition of Nitrogen Trichloride by Chlorine, and the Induction Period of the Hydrogen Chlorine Reaction: J. G. A. Griffiths and R. G. W. Norrish.
The Photosensitised Formation of Hydrogen Peroxide in the System Hydrogen-Oxygen-Chlorine: R. G. W. Norrish.
The Photochemistry of Mixtures of Chlorine, Oxygen and Carbon Monoxide: Prof. G. K. Rollefson.
The Mechanism of the Photo-Oxidation of Gaseous Alkyl Halides: J. R. Bates and R. Spence.
A Comparison of the Efficiency of Photochemical Reactions and Similar Reactions Produced by Gaseous Ions: G. R. Gedye.
Saturday, April 18, at 10 A.M.—Photochemical Change in Liquid and Solid Systems.
Introductory Paper: Prof. A. Berthoud.
The Photochemical Temperature Coefficient: D. W. G. Style.
The Acceleration of the Electrolytic Deposition of Hydrogen and Oxygen by Light of Short Wave Length: Dr. F. P. Bowden.

Scientific Medicine

MUCH of the more important subject matter of the annual report of the Medical Research Council recently published, and dealt with elsewhere in this issue (p 598), was brought to public notice by the newspapers as occasion arose The establishment at University College Hospital of a department of clinical research is an example Scientific results achieved or foreshadowed during the year under review were many and valuable, and to be able to say of such a year that it "illustrates the general features that have marked the progress of modern medical investigation throughout the world during the present generation" is an indication of solid attainment Nevertheless, there are two sides to progress —progress in discovery and progress in organisation , and the phrase quoted is strictly relevant to an argument concerning the machine and its design rather than its output

This argument, unobtrusive but intense, affords an answer to professional criticism, which, having filled out its voice in the correspondence columns of the *Times*, died away again last summer, its 'airy swellings', unlike the music in 'Endymion", unrevived They will be revived sooner or later, for the sufficient reason that "the study of disease as such is by no means the only field of medical research it is a field indeed that work in all the other fields is actually aimed at reducing" For the time being, the Medical Research Council resolves this dualism within its own organisation but it cannot resolve it elsewhere It holds a balance between the claims of investigations which lead at best to results of professional and technological value and the claims of what the authors of the report call the "intensive pursuit of the more primary studies" that serve medical science

Fortunately from an evidential point of view, unfortunately otherwise, what sort and standard of investigation is deemed specially desirable by the Council's critics is revealed by the plans in existence for a research laboratory in the grounds of Charles Darwin's house, where young men waiting for hospital appointments are to wait less unprofitably than they wait now Since a feather would turn the Council's scale in favour of applications, and since the existence of a laboratory for experimental surgery might as easily increase as diminish the clamour for a more professional outlook, it is not to be counted altogether a gain that the poise within the Council itself is so delicately adjusted

Work accumulates faster than funds Increasing responsibilities are laid upon the Council by the growth of work within the range of the Therapeutic Substances Act "This growing burden depends in part upon the advisory relations of the Council to the routine administration of the Act For the rest, it consists in the active promotion of research work concerned with the preparation and use of standards of reference for the proper assay of biological substances" It is urged that such work for the protection and assistance both of the public and of the medical profession is valuable Of course it is, and so is the part played by the League of Nations in gaining international adherence to common standards It is urged that the Council is charged by Parliament with the duty of aiding 'from a narrowly limited fund whatever, being needy, is most fruitful and most hopeful" either in applications or in fundamentals, and that this duty is onerous Of course it is It is urged that the curative work of the physician or surgeon is vitally important but is not the sole concern of medicine, which increasingly, step by step as knowledge advances, is concerned "with the sciences and arts of preventive work in all its kinds" "The science of nutrition, newly born almost within this generation, is bringing into sight new possibilities of greatly augmenting the preventive services of medicine and of setting in the middle of the picture not so much the attack upon declared disease as the establishment of right development and full health" The management of life, in industry and in the home, replaces the control of active disease

It is harder to delimit the boundaries to be set to medical research than to describe its major concerns The Council gives up the attempt, falling back upon the words of the Ormsby-Gore Research Co ordination Sub Committee "Medical research deals by no means only with the cure of disease It deals with the proper development and the right use of the human body in all conditions of activity and environment as well as with its protection from disease and accident and its repair"

Scientific medicine is no longer preoccupied by disease, which was "the earliest preoccupation of medicine" Yet the report asks us to "think of it" as being still so preoccupied, in order that we may appreciate the dependence of the modern clinical worker "more and more upon the tools and methods of the laboratory" Problems are taken from the bedside to the laboratory for their solution and there new problems are distilled for exploitation in the clinic Was Emerson the origin of this compensatory theme? "It is thus written, because it is thus in life Our action is overmastered, and characterised above our will by the law of nature We aim at a petty end quite aside from the public good, but our act arranges itself by irresistible magnetism in a line with the poles of the world" At all events, Emerson was equal to the theme to the end If "an inevitable dualism bisect nature", compensation lurks "the man or woman who would have remained a sunny garden flower, with no room for its roots and too much sunshine for its head, by the falling of the walls and the neglect of the gardener, is made the banian of the forest, yielding shade and fruit to wide neighbourhoods of men"

It is to be hoped that the compensatory ingenuity of the Medical Research Council will equal the transcendentalist's in compassing the termination of its theme when the time comes But that is not yet "By far the greater part of the work the Council aid or initiate is done within the Universities or in Hospitals serving Universities In this way the work gains not only from the intellectual freedom that belongs to University life and the opportunities that it brings of stimulating and recruiting youth, but it gains also by the use of material resources derived from other funds, both public and private, ancient and recent, without which not one half of the work now to be described could have been sustained" The weights are indeed exquisitely poised It is, however, a wholesome reminder of realities to turn back a page or two to the confession that the contrasted (not compensatory in this case) tendencies of modern medicine, the extensive and the intensive, must each "bring its own difficulties" Nevertheless, it cannot be said that these have been obscured for readers familiar with them

The Council, it seems, is marking time It has arrived, as it were, at a definite stage in the race, the egg still in the spoon Hints of future policy are scarcely discernible A year ago there was some expectation of a policy of centralisation It is not suggested in these pages Praise of the universities is mere 'thank you', and gratitude is not always a vivid sense of benefits to come Clinical research is policy active, and assay of biological substance an obligation Policy waits on politics and the exchequer whether England will prefer to receive modernisation at the hands of M André Siegfried or Sir Oswald Mosley or will prefer not to receive it at all It is all very well for Germans to remember "as an object-lesson of the conception of the State's functions,

that Prussia founded the University of Berlin in the days of her deepest political depression ", in the words of General von Seeckt Germany is not England, but a country that believes in what it calls "geistige Macht" Abraham Flexner ("Universities, American, English and German") may be right, and "To be frank, despite their great scholars and scientists and ours this sort of thing does not come easy to either Great Britain or America"

Flexner, an acute, if strongly individualised observer of the state of scientific organisation the world over, has it on the same page "The creation of the University Grants Committee, the Medical Research Council, the Department of Scientific and Industrial Research indicates recognition of the fact that England lacks modern universities The organisations just named give temporary relief—a block grant, support for a promising investigator or an important investigation Such agencies are not superfluous, under all circumstances they have their uses, but they are no substitute for universities, amply endowed, amply equipped, and amply attended by a sufficient group of men and women dedicated to the search for truth They seem to say 'We lack developed universities While we are waiting for them or in preparation for them, let us train this or that promising man, let us get this or that thing done' It is all very well, but it does not answer" He calls the Medical Research Council "the one mitigating factor of importance" in Britain's unorganised and undeveloped resources in scientific medicine, and in this report we have the measure of its mitigation

Egyptian Mathematics

Mathematischer Papyrus des Staatlichen Museums der Schönen Künste in Moskau Herausgegeben und kommentiert von W W Struve Unter Benutzung einer hieroglyphischen Transkription von B A Turajeff (Quellen und Studien zur Geschichte der Mathematik, Abteilung A Quellen) Pp xii + 198 + 10 Tafeln (Berlin Julius Springer, 1930) 48 80 gold marks

THIS edition of the Moscow papyrus (complete with plates giving photographs of the whole of the text and a hieroglyphic transcription) has been eagerly awaited by Egyptologists and historians of mathematics alike The volume is finely produced, and we can only congratulate the author upon the result of some three years' intensive study of the papyrus and all the literature of the subject of Egyptian mathematics Egyptologists will in due course have much to say upon it, the present notice will deal with it from the point of view of the mathematician only

The papyrus, now in the Museum of Fine Arts at Moscow, formerly belonged to Vladimir Golenischchev, who bought it in Egypt in 1892–93 or 1893–94 It is said to have come from the necropolis of Dra Abū'l Negga, in the immediate neighbourhood of the place where the Rhind papyrus was found, namely, in the ruins of one of the small buildings near the Ramesseum Written during the Thirteenth Dynasty, it was copied from an original of the middle of the Twelfth Dynasty, slightly earlier, if anything, than the original of the Rhind

We have known something of the content of the papyrus since Turaiev published in *Ancient Egypt*, 1917, a paper on "The Volume of the Truncated Pyramid in Egyptian Mathematics" (problem No 14 in Struve's numbering) A further paper by Zinzerling published in 1925 contained the translation and transcription by Turaiev of four more problems from the papyrus, three of which are geometrical These three problems, together with that of the truncated pyramid, are the subject of a long and important article by Battiscombe Gunn and T Eric Peet in the *Journal of Egyptian Archæology* (vol 15, 1929, pp 167 185) As compared with the Rhind papyrus, the Golenischchev papyrus shows certain differences Whereas the Rhind, although severely practical (there is only one hint in it of a general formula), has its problems arranged in distinct groups and is apparently a kind of handbook of instruction, the Moscow papyrus, where the problems are arranged anyhow, is more like an examination paper (with solutions), the suggestion of the editor is that it was in use, in a school for scribes, as a kind of test paper The problem is given to the pupil by the scribe teacher, "If thou art asked do so and so", the working is supposed to be shown by the pupil to the teacher, sometimes with the word "See!" added, and the teacher replies, "Thou hast found it correctly' The concrete numbers chosen for illustration are as simple as possible, so that there is none of the complicated arithmetical work which we find in the Rhind

The problems (twenty five in number) are re-arranged by the editor in groups (1) 'cooking ratio' problems relating to the interchange of loaves and measures of beer according to the 'strength' of each, (2) simple rule of three problems, (3) 'hau' calculations corresponding to equations in one unknown, (4) problems of finding areas and volumes We have also in the papyrus the operations of

squaring and finding the square root, which do not appear in the Rhind A typical problem is to find the sides of a rectangle (or a right angled triangle which is the half of a rectangle), when the area and the ratio of the sides are given This leads to the equivalent of an equation of the form $(m/n)x^2 = A$ m/n is, of course, expressed as the sum of submultiples, for example, $\frac{1}{2} + \frac{1}{4}$ In one case $m/n = \frac{1}{2} + \frac{1}{4}$ and A is 12 The Egyptian says, "Reckon with $\frac{1}{2} + \frac{1}{4}$ to find 1 (that is, he divides 1 by $\frac{1}{2} + \frac{1}{4}$ or $\frac{3}{4}$) result $1\frac{1}{3}$" He then multiplies 12 by $1\frac{1}{3}$, making 16, and extracts the square root of 16 result 4 Thus the side we have called x is 4, and the other side is $(\frac{1}{2} + \frac{1}{4})$ 4 or 3

Of outstanding interest is the problem No 14, which, as indicated above, gives the correct com putation of the content of a frustum of a pyramid with square base, cut off by a plane parallel to the base (in the particular case the side of the square base is 4, the side of the opposite face 2, and the height 6) In accordance with the correct formula $\frac{1}{3}h(a^2 + ab + b^2)$, where h is the height and a, b the sides of the square base and top respectively, the Egyptian says, in short, "Square 4 (the side of the base), result 16 Double 4 (that is, multiply the 4 by 2, the side of the upper square) result 8 Square 2 result 4 Add $16 + 8 + 4 = 28$ take $\frac{1}{3}$ of 6 (the height), that is 2 reckon with 28 twice (that is, multiply the 28 by the 2) See! we have 56 Thou hast reckoned correctly" How came the Egyptian by the correct formula? The question is discussed at length by Gunn and Peet in the paper referred to, and we may expect it to give rise to much further speculation The formula can be obtained by algebra (or its equivalent in the shape of mensuration) in two ways (1) by regarding the frustum as the difference between two similar pyramids with square bases, (2) by drawing perpendiculars to the base from the four corners of the square top and so splitting up the figure into (a) a right parallelepiped with base a^2 and height h, (b) four prisms, each of which has for one face one of the erect faces of the parallelepiped, and (c) four small pyramids at the corners, with square bases, each of which has $\frac{1}{2}(a - b)$ for its side The second method is, *mutatis mutandis*, that of Heron's "Metrica", II 8, and the first that of II 7 In either case we must know the formula $\frac{1}{3}a^2h$ for the volume of a pyramid with base a^2 and height h The equivalent of this is obtained by Euclid in Props 5 7 of Book XII by the method of exhaustion, the ancient substitute for the calculus It is not conceivable that the Egyptians had attained to this order of ideas. On the other hand, for the purpose of constructing their pyramids, they had the greatest practical interest in knowing the amount of material that would be required for a pyramid of given dimensions Actual experience would in time give a rough guide, and they could easily arrive at an expression for the content of a pyramid by measuring how much corn, or what not, would go into a vessel of that shape, for they must have seen that the height and the area of the base would come into the calculation Struve agrees that the Egyptians must have arrived at the formula for the complete pyramid in some such practical way, the rest of the calculation for the frustum would offer no insuperable difficulty

The Egyptian achievement is the more remarkable when compared with other ancient attempts to solve the problem A primitive mathematician would naturally think of multiplying the height by some mean area, the formula thus obtained might be $\frac{1}{2}(a^2 + b^2)h$ or $\{\frac{1}{2}(a + b)\}^2h$ The former approximation is found in the "Stereometrica" attributed to Heron, it is parallel to, and may have been suggested by, a similar formula for the volume of a frustum of a cone used by the Babylonians about 2000 B C The second is found in Brahmagupta, as well as in the "Stereometrica" Improving on these cases, Kurt Vogel has recently suggested in the *Journal of Egyptian Archæology* that the Egyptian may have thought of multiplying the height by the average of *three* areas, a^2, ab, and b^2, that is, $\frac{1}{3}(a^2 + ab + b^2)$ but it seems in the highest degree unlikely that this would occur to anyone who did not know the formula beforehand

Space does not allow us to discuss the other remarkable problem (No 10), where, if the interpretation is right, and assuming the known Egyptian estimate of the value of π, namely, $\frac{256}{81}$, the author seems to calculate correctly the surface of a hemisphere, whereas, so far as we know, Archimedes was the first person to prove scientifically that the area of the surface of a sphere is equal to four times the area of a great circle in it

An important result incidentally obtained by Struve relates to the once disputed question whether certain triangles in problems 51 and 52 of the Rhind papyrus are right angled or isosceles He shows from the problems in the Moscow papyrus that in the case of the right-angled triangle the perpendicular sides are called by names which mean 'length' and 'breadth' as in a rectangle, whereas in problem 4, which is identical with No 51 of the Rhind, the area of the triangle is obtained as the product of the 'tp r' and the 'mryt', the

same terms as those used in the Rhind The triangles in the Rhind are therefore not right-angled, and Struve concludes, like Peet and Gunn, that they are isosceles, like them, too, he arrives (though by a slightly different route) at the conclusion that, while 'tp-r' means the 'base', 'mryt' can only be the perpendicular height (as it must be if the formula used is correct), and not one of the sides other than the base T L H

Physical Chemistry applied to Biology

(1) *Colloid Science applied to Biology a General Discussion held by the Faraday Society, September–October, 1930* Pp 659 865 (London The Faraday Society, 1931) 12s 6d

(2) *Precis de chimie physique à l'usage des etudiants en médecine* Par Prof Fred Vlès Pp vii+414 (Paris Vigot frères, 1929) 50 francs

(1) THE Report of the Faraday Society's General Discussion at Cambridge on "Colloid Science applied to Biology" is a substantial volume, containing more than 200 pages The twelve papers which were presented to the meeting only occupy about 120 pages, so that the discussion is responsible for the other 80 pages This is an accurate reflection of the fact that a lively discussion was maintained during a series of sessions covering two complete days, of which only a small part was occupied by the presentation of papers which had already been circulated in advance The keenness of the discussion, and the large number of eminent research workers who took part in it, provided a remarkable vindication of the recently adopted policy of the Faraday Society in undertaking the organisation of a discussion on colloid science in alternate years, but it also demonstrated, in an even more emphatic way, the value and importance of a meeting at which biologists on one hand and chemists and physicists on the other hand could meet on neutral ground to discuss problems for the solution of which co-operative effort from both sides is obviously needed

The widespread belief that the study of living matter may in the near future lead to even greater advances than those which have resulted during the past twenty years from the study of atomic structure, emphasises the urgency of this co-operation, and indicates the liberality of the crop that is waiting to be harvested From this point of view special interest is attached to the 'introductory remarks' on "The Structure of Living Matter", by Sir F Gowland Hopkins, and to the 'conclusion' of Sir William Hardy, neither of which has hitherto appeared in print The former directs attention to the almost absolute neglect of colloid science in the decade 1887–97, and the awakening of activity which followed the appearance of Hardy's papers in 1899 and 1900, but it also includes a warning that the problems presented by living systems are very complex, and that it is essential to keep in touch with the reality that is inherent in that complexity, since artificial colloidal systems do not and cannot "display, save in some accidental and unreal aspects (of which the importance is often exaggerated), the attributes of life" Sir William Hardy also urges that "at the present moment biology is overcharged with facts", and points out the "prodigious services" which could be rendered by a mathematical physicist who had sufficient courage to "leave his home in the physical laboratory" and "come over the way" to "live with biologists under the same roof"

If the Faraday Society had done nothing more than provide a platform from which the urgency of this call could be announced, the organisation of the meeting and the publication of the present report would have been sufficiently justified, the fact that the meeting was held in Cambridge may, perhaps, be interpreted as in some sense a challenge to the University to undertake the leadership in a new period of advance in natural knowledge

(2) The modest volume of Prof Vlès is at the same time an introduction to physical chemistry and a store of information as to its applications to biological problems It could only have been written by a physical chemist who had taken up his abode in a biological environment and thus acquired an interest in and an insight into the bewildering problems of living matter From this point of view, the fact that Dr Vlès has been attached for some years to the faculty of medicine in the University of Strasbourg, instead of holding a general chair of physical chemistry, provides a sufficient explanation of the fact that the biological aspects of the subject really dominate the whole book, instead of being mere addenda to serve as a 'bait' to entrap the interest of the medical student, or 'sugar and spice' to tickle his palate when engaged in the compulsory study of an unpalatable subject The sympathetic introduction written by the dean of the Faculty of Medicine is more than justified by the whole heartedness with which Prof Vlès has devoted himself to his task

The book itself is divided into three parts, dealing mainly with osmosis and related properties of solutions, electrical properties of solutions, and the colloidal state, but there are two appendices, one

dealing with interfacial charges and the stability of suspensions and the other with the physical chemistry of bacteria and of the fluids of the body The second appendix covers more than fifty pages and represents a course of lectures which has been delivered annually to the Faculty of Science during the past ten years It is of a different character from the earlier sections of the book, where the primary object is to give instruction in physical chemistry, since its main purpose is to describe the advances in knowledge which have been made as the result of the application of physico chemical methods of investigation to biological problems Those who heard the recent Croonian Lecture will be interested to note the references made to the work and theory of Bordet on toxins and anti toxins, but there is also a number of references to the author s own experimental observations

The book is issued in a cheap and unpretentious form Its importance depends not merely on the immediate value of the material which it contains, but also on the evidence which it affords of a growing collaboration between physicist and biologist in the difficult but fertile study of living matter

Index Londinensis

Index Londinensis to Illustrations of Flowering Plants, Ferns and Fern Allies, being an emended and enlarged edition continued up to the end of the Year 1920 of Pritzel s Alphabetical Register of Representations of Flowering Plants and Ferns compiled from Botanical and Horticultural Publications of the XVIIIth and XIXth Centuries Prepared under the Auspices of the Royal Horticultural Society of London at the Royal Botanic Gardens, Kew, by O Stapf Vol 3 Pp iv + 555 Vol 4 Pp iv + 568 Vol 5 Pp iv + 549 (Oxford Clarendon Press, London Oxford University Press 1930–1931) £5 5*s* net each vol

VOLUME 3 of this work appeared in June 1929 It contains 555 pages and references to illustrations of all plants from *Earina* to *Justicia* inclusive Volume 4 was published in October 1930 It consists of 568 pages and references to plants from *Kadsura* to *Pedicellia* inclusive Volume 5 appeared in February 1931 In its 549 pages are to be found references to illustrations from *Pedicularis* to *Sapium* inclusive Thus, such important genera as *Pelargonium*, *Pinus*, *Pirus*, *Primula*, *Rhododendron*, and *Rosa* are included As exemplifying how the same species may occur under different generic names in different parts of the "Index", *Pelargonium pallens*, *P parviflorum*, *P zonale*, and others are found under *Geranium* in Vol 3, *Prunus Padus* occurs as *Cerasus Padus* and *Potamogeton palustris* as *Comarum palustre* in Vol 2, *Rhododendron indicum* as *Azalea indica* in Vol 1, and so on Names are always quoted just as the author gives them from whose work the references are taken, and this necessarily involves the quotation of references to the same species in different volumes

Sound orthography and grammatical correctness and consistency, though matters of minor importance, should not be conspicuous by their absence in a work of this nature, and the "Index", on the whole, sets a good example in this respect It will be noted that tree names ending in *us* which have come down from the old classical writers, such as *Quercus*, *Pinus*, *Rhus*, *Sambucus*, are of feminine gender, while those of recent origin, such as *Phyllanthus*, *Podocarpus*, *Pterocarpus*, are masculine Again, the more correct spellings "*Pirola*" and "*Pirus*" are used in preference to "*Pyrola*" and "*Pyrus*" so commonly in vogue *Ranunculus acer*" is the name adopted for the common buttercup rather than the ungrammatical "*R acris*" used by Linnæus, and this seems quite logical, but in the case of *R palustris*, the form *paluster*" would have been more consistently correct The fact that some rather obscure classical authors, like Ennius and Columella, have used the forms "*acris*" and "*palustris*" for the masculine gender, cannot alter the matter

A few of the features of the "Index" may be referred to here In accordance with the most recent views, many of the old comprehensive genera have been broken up, so that, for example, in the case of the grass *Festuca*, there are now 25 recognised genera which formerly were all included in this genus These are all arranged alphabetically and numbered in sequence after the heading "*Festuca* Auct ", and to each species cited under it a number is attached indicating to which genus it properly belongs, thus, *F duriuscula* is a true *Festuca* as understood by Linnæus, but *F inermis* is a *Bromus* On the other hand, there are other genera, such as *Bucetum* and *Gouinia*, which have been called *Festuca* but are not truly such There is thus the second heading *Festuca* Linn, followed by "Vide *Bucetum*, *Gouinia*, etc " Other genera in these volumes have been broken up in the same way, such as *Echinocactus*, *Gnaphalium*, *Orchis*

In the "Index" will be found numerous references to Blanco's "Flora of the Philippines" (3rd edition, 1878–80) Blanco was only an

amateur botanist and many of his illustrations are erroneously named The American botanist Merrill has issued a corrected list of Blanco's names Hence, for each incorrectly named illus tration in Blanco there are in the " Index " two distinct references, one giving Blanco's name and the other the correct name 'fide Merrill ", and in each case a cross reference to the other is supplied

In some botanical works, the names on the plates are different from those in the text referring to the same plant This may be due to the fact that the plates were labelled and printed some time before the text was written, when different ideas of nomenclature had prevailed in the author's mind In these cases, again, there are two dis tinct headings in the " Index ", with the necessary cross-reference in each

In John Hill's 'Family Herbal ", dated 1812, the illustrations are mostly very crude, and often names quite foreign to our modern ideas have been given to the plants In these cases the editor has interpreted the plants figured in terms of modern nomenclature For example, *Malva moschata* is called in the book " Vervain Mallow Alcea " Every reference in the "Index" giving the correct name is always followed by the phrase " fide Ed "

An interesting use to which the " Index " might be put would be the tracing of the evolution of the art of depicting any well known or common plant But references to pre Linnæan pictures should, in most cases, be sought for elsewhere than in the " Index " W C W

Our Bookshelf.

Sexual Reform Congress, London, 8 14 IX 1929 W L S R World League for Sexual Reform Weltliga fur Sexualreform Ligue Mondiale pour la Réforme sexuelle Tutmonda Ligo por Seksaj Reformoj Proceedings of the Third Congress Bericht des dritten Kongresses Compte rendu du troisième Congrès Dokumentaro de la tria Kongreso Edited by Norman Haire Pp xl + 670 + 8 plates (London Kegan Paul and Co, Ltd, 1930) 25s net

THE Report of the Sexual Reform Congress held in London in September 1929 contains material of interest to men of science as well as to those concerned with social and moral problems The reader will possibly turn first to Dr Norman Haire's own paper on " Sterilisation, Abortion, and Birth Control ", and will also read with interest Dr Ernst Grafenberg's exposition of his silver ring method of preventing conception Dr Franz E Hirsch's paper on the use of blood tests as indications of paternity, is also of interest, and the method seems to him to be capable of yielding fairly definite results Dr M D Eder, on the " Sterilisation of the Unfit ", is rather doubtful as to the effectiveness of such methods in the present stage of our knowledge We doubt, however, if eugenists will allow themselves to be thus discouraged Dr Bernard Hollander, in his paper, Insanity and Divorce ", urges the amendment of the law so as to allow divorce for incurable insanity

Capt G Pitt Rivers, in his paper, " Sex phobia and Marriage ", claims to have established the interesting and (if true) highly important fact that dense and increasing populations tend inevitably to yield a surplus of women This lends additional interest to Miss R B Kerr's remarks on the " Sexual Rights of Spinsters " The writer claims that the increasing body of women who can afford to bring up one, two, or three children themselves, without the aid of any man, 'should at once be sexually free " Another interesting paper, especially to medical men, will be that of Dr Abraham Stone on " Pre Marital Consultation ", though much of it is a counsel of perfection, at the present time

The value of the papers in this collection naturally varies Feeling themselves under a cloud of opposition, the writers occasionally adopt a propagandist attitude, and here and there we find traces of rhetorical treatment--not so glaring, however, as we should find in the writings of those who take the conservative side in sex affairs On the whole, however, the scientific attitude may be said to prevail J C HARDWICK

Monographs of the Geological Department of the Hunterian Museum, Glasgow University 4 Reports on Geological Collections from the Coast lands of Kenya Colony made by Miss M McKinnon Wood With Introduction by Dr J W Gregory and Report on the Ammonites by Dr L F Spath, Report on the other Mesozoic Mollusca and Brachiopods by Dr J Weir, Report on the Kainozoic Mollusca by L R Cox, Report on the Cheilostomata by Dr H D Thomas, Report on the Echinoidea by Dr Ethel D Currie, Report on the Corals by Dr J W Gregory, Report on the Ostracoda and Foraminifera by Mary H Latham, Report on the Fossil Plants by Dr S Williams, Report on Igneous Rocks by Agnes Neilson, and on the Stratigraphy of the Kenya Coastlands and a List of Localities by Meta McKinnon Wood (Glasgow University Publications, 17) Pp vi + 232 + 24 plates (Glasgow Jackson, Wylie and Co, 1930)

THE fossils described in this monograph were collected by Miss M McKinnon Wood from an area extending from 20 miles north of Malindi to about 15 miles south of Mombasa and stretching inland for 30 to 40 miles along the Kenya-Uganda railway The fossiliferous deposits dip gently toward the coast and are of Jurassic, Cretaceous, Miocene, Pliocene, and post-Pliocene ages The oldest formation of the coastal sedimentary deposits

is the Duruma Sandstone, from which only a few non marine fossils, affording but little evidence of age, were obtained It is thought that this sandstone is mainly of Triassic age, but the lower part is probably equivalent to the Karoo Beds of South Africa

The Jurassic deposits consist of shales and lime stones which, from the evidence of the Ammon ites, appear to range in age from Bajocian to Kimeridgian The Cretaceous is represented by the Freretown limestone, which is regarded as of Urgonian age The Tertiary deposits form a narrow strip along the coast, widening out to the north Of these, the Funda Isa limestones of Lower Miocene age (Aquitanian Burdigalian) contain a molluscan fauna closely related to that of contemporaneous deposits in Madagascar, Persia, and India, but a small number of the species are known to occur in the Lower Miocene of the Mediterranean region and indicate that some communication must have existed between the two regions The North Mombasa Crag is of Lower or Middle Pliocene age The mollusca in the post-Pliocene deposits belong mainly to species which are widely distributed throughout the Indo Pacific province, but include three species which are not known to be living on the west side of the Indian Ocean

The Year Book of the Scientific and Learned Societies of Great Britain and Ireland a Record of the Work done in Science, Literature and Art during the Session 1929–1930 by numerous Societies and Government Institutions Compiled from Official Sources Forty-seventh Annual Issue Pp vii + 384 (London Charles Griffin and Co, Ltd, 1931) 18s net

Messrs Charles Griffin and Co, Ltd, deserve the thanks of scientific workers generally for the money and care they have expended during the past half century on the production of this useful reference book This, however, is to be the last time we shall be able to welcome its appearance—at least, in its present form For those who are unacquainted with the volume, we may say that it contains particulars as to the names, addresses, meetings, membership, and publications of the scientific and learned societies of the British Isles and of Government scientific departments, and to each society, where the information is available, is appended a list of the papers read during the session 1929–30 The societies are classified by their subjects The information given is 'official' in the sense that it is supplied by officials, honorary or otherwise, of the societies, institutions, and laboratories dealt with, and we are grateful for the trouble they have taken

Future issues of the book will be shorn of the lists of papers We are sure this is a wise decision Even though the lists are the latest available to the compilers, the titles of papers read during the session 1929–30 seem out-of date in a reference book issued in 1931, and by their omission the size of the volume and cost of production should be considerably reduced This in turn should react favourably on the sales, for the essential part of the book for reference purposes will remain We hope it will be possible to retain the distinctive and serviceable binding in the new series

A Handbook of English in Engineering Usage By Prof A C Howell Pp vii + 308 (New York John Wiley and Sons, Inc, London Chapman and Hall, Ltd, 1930) 12s 6d net

It is seldom that a book appears which can be regarded as unique in the subject matter with which it deals, but this may be truly predicated of Prof Howell's engrossing work It is a shining example of the principles enunciated, and it is pleasant to peruse the flowing periods and incisive remarks permeating the pages The advice that a writer should project himself into the reader's position is well urged A fault to which attention may be directed, however, is that the text is unduly protracted, and there is a tendency to reiteration In places, too, are encountered erroneous examples on phrasing—such as "The message will be delivered to *whoever* is authorized", "The kind of *pens* is the best", "*one* must write *his* paragraph" may be cited For a book on engineering phraseology there are too many examples of non engineering sentences given as illustrations The author's remarks on reviewing, editorials, and cognate matters are inspiring In a work like the present, the use of "*the same* letter", when "*a similar* letter" is intended, would not be expected In conclusion may be commended the maxim on p 93, "There is a vast difference between having to say something and having something to say" P L M

Vertebrate Embryology By Prof Waldo Shumway Second edition, thoroughly revised Pp x + 311 (New York John Wiley and Sons, Inc, London Chapman and Hall, Ltd, 1930) 18s 6d net

The text-book of vertebrate anatomy by the professor of zoology in the University of Illinois was so eminently useful, being concise and lucid, and illustrated by an adequate number of very clear diagrams, that it is not surprising to record the appearance of another edition, which has been revised and improved It provides an account of the early development of *Amphioxus*, the frog, the chick, and man, the formation of their germ-layers, embryonic membranes and bodily form, and an excellent section dealing with organogeny The third part of the book consists of a very instructive atlas of sections, which includes drawings of a valuable series of pig embryos Part four is concerned with technique and deals with the preparations of embryological material, the use of the microscope, the making of drawings, and reconstructions

This book can be recommended to any demonstrator of zoology or anatomy who wishes to provide a course that is well adapted to the needs of the medical student In those laboratories which are so fortunate as to possess the necessary embryological material, the book will serve as an excellent guide to the student

An Egyptian Axe-head of date 1800 B C its Investigation and Reproduction

SOME months ago, Mr Guy Brunton asked me whether I would examine and report upon an Egyptian axe head It was one of several specimens of the same date He was so good as to give me permission to destroy this particular specimen if it was necessary in the interests of a full scientific investigation This examination I have now been able to complete, and it may be of interest if I add that, except in one particular—and this, I think, would only be noticed by experts—the specimen has been in no way injured I emphasise this, because the natural objection to their injury or destruction is the reason why so few investigations have been allowed to be made of ancient metal specimens

FIG 1 ×7

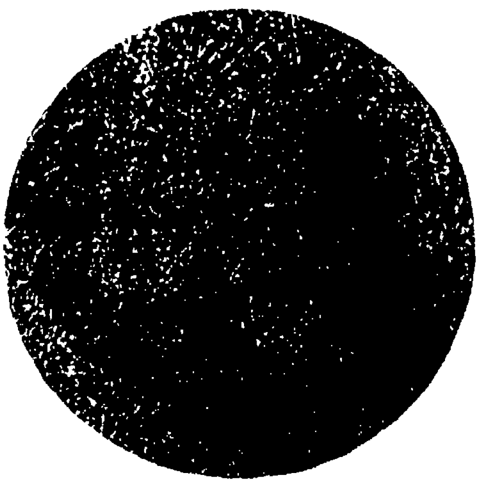

FIG 2 ×7

The axe head, the outline of which is shown in Fig 7 (× ⅓), was coated with a green patina This bore the pattern of the fibre wrapping in which it had been enclosed It was removed by means of a wire brush with dilute hydrochloric acid Underneath was a thin layer of cuprite which coated the metal This also was removed The metal itself was copper-coloured, but etching with ammonium persulphate developed a dendritic structure on the surface which showed that the material was not pure copper but an alloy of high copper content The appearance of the deeply etched surface at a magnification of 7 diameters is shown in Fig 1 The dendritic structure also showed that the axe head was made from 'cast' material and the fact that the dendrites were not appreciably distorted showed that it was cast and not forged to shape Even at its edge there was no evidence of severe working, as is shown in Fig 2

FIG 3 ×100

At higher magnifications it was seen that the metal had completely recrystallised and that the resulting crystals were twinned This showed that the casting had been worked to some extent and had been annealed during or after this treatment These twin crystals are shown in Figs 3 and 4 at 100 diameters magnification The dark markings (called 'cores') represent some of the original structure of the specimen

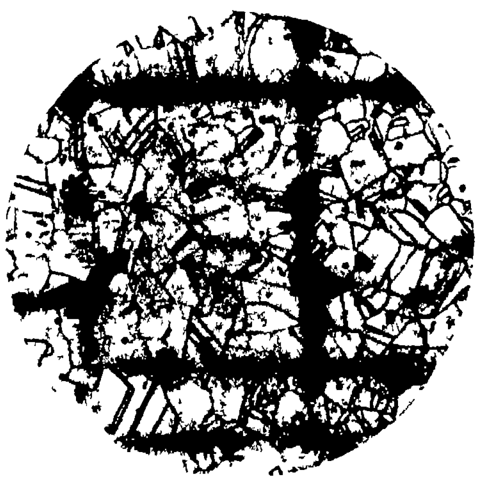

FIG 4 ×100

and constitute definite evidence that it is an alloy Speaking broadly, the recrystallised grains were undistorted, but some of the twin bands were slightly bent, as is clearly shown in Fig 5 at 250 diameters magnification This slight local distortion of the structure indicates that the annealed axe head had been subjected to a comparatively mild and rather uneven form of cold working, such as hammering

Fig 5 ×250

The Brinell hardness of the axe head varied from about 90 on the flat to 112 at the edge The hardness, measured with a 1 mm diameter ball, varied considerably from place to place on the surface, indicating either that the axe head was not homogeneous or that it had been unevenly work hardened Both these conclusions are in agreement with the microscopic evidence The hardness measurements are shown in Table I and in Fig 7

Chemical analysis showed that the axe head contained 96 9 per cent of copper, 1 5 per cent of arsenic, 0 7 per cent of iron, and 0 2 per cent of tin The remaining 0 7 per cent included small quantities of nickel, sulphur, and oxygen

An experiment was then made to reproduce the axe head An alloy of the same shape and composition was cast in sand and was then subjected to the mechanical and thermal treatments which the microscopic and hardness data indicated the Egyptian axe head had received First of all, the casting was hammered lightly with a 7 lb hammer It was then annealed for periods of 15 minutes at intervals of 50° C from 400° C upwards until the metal recrystallised and the crystal grain size became approximately the same as that of the axe head This occurred at 700° C The pronounced "coring" of the cast alloy became less distinct as the annealing temperature was raised, and at 700° C was comparable with the structure of the axe head The annealed alloy was finally re hammered Brinell hardness measurements of the alloy were made at all stages of the above treatments They are shown in Table I

Table I

Material	Treatment	Hardness		
		Maximum	Minimum	Average
Axe head	As received	112	82	97
	Annealed at 700° C	61	54	57
Copper arsenic iron tin alloy of the same composition cast in the laboratory	As cast	60	53	56
	Hammered	106	86	96
	Annealed at 700° C	63	56	59
	Re hammered	103	82	93

As will be seen from the table, the hardness of the re hammered alloy agreed satisfactorily with that of the axe head

Fig 6 ×250

The microstructure of the re hammered casting is shown in Fig 6 at 250 diameters magnification A comparison of the crystal grain size, the distortion of the twin bands, and the unevenness of the etching (which represents the coring in this photomicrograph) with the corresponding features in Fig 5 shows that the alloy synthesised in the laboratory markedly resembled the axe head both in microstructure and in hardness

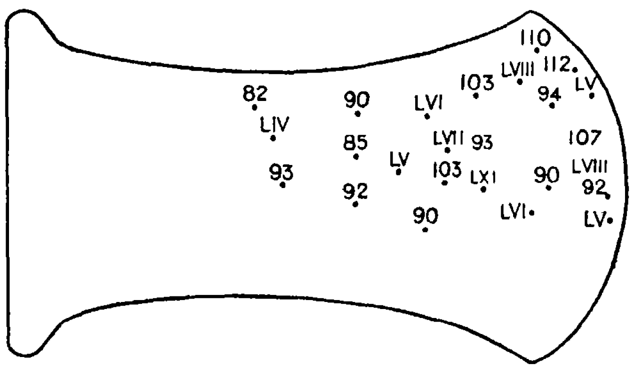

Fig 7 —Outline of axe head • Brinell hardness 1 mm ball, 10 kgm load As received, Arabic numbers annealed Roman numbers

The experiments all lead to the conclusion that the Egyptian axe head was cast to shape, worked to some extent—no doubt by hammering—and annealed at about 700° C either during or after the mechanical working In order still further to test these deductions, the axe head itself was annealed at 700° C for 15 minutes and its Brinell hardness then measured The readings which are shown in Table I (line 2) are in good agreement with those of the annealed casting (line 5)

The hardness at various points on the surface of the axe head before and after annealing are shown in Fig 7 It will be noticed that the hardness of the edge, originally as high as 112 Brinell, was reduced to about 55 by annealing It was thus approximately halved This means that the work hardening capacity of the alloy is high Although the maximum hardness of the edge is somewhat surprising, considering the low

alloy content of the copper and the comparative mildness of the cold working, it is not so high as to lend support to the view that the Egyptians possessed a method of hardening copper with which we are unacquainted The hardness of the axe head was produced partly by alloying and partly by cold working By a suitable choice of alloying elements and more effective mechanical treatment, much greater hardness can be produced to day

One further conclusion may be drawn This investigation has made it possible to answer the question whether hardening by cold work is permanent in an alloy of this type at the ordinary temperatures According to Mr Brunton's view, the axe head is more than 3700 years old When I discussed this question with him and the extent to which this date might be in doubt he was willing to advance it 200 years but no more Accepting this, its age is at least 3500 years No one, of course can say whether it has lost any of its original hardness, but it is quite clear that it has retained a considerable amount of work hardness throughout this long period

I wish to acknowledge the assistance of two members of my staff, Mr C W Dannatt and Dr M S Fisher, in the above investigation

Constitution of Rhenium

OWING to the kindness of Dr Noddack who provided me with a sample of the heptoxide of his recently discovered element rhenium, I have been able to obtain its mass spectrum Re_2O_7 is a slightly volatile greenish crystalline solid Its vapour was first admitted to the discharge like that of osmium tetroxide, but with no success The solid was then introduced into the discharge tube and heated in the cathode ray beam, but although the volatilisation was ultimately such as to cause a visible dark layer on the surrounding walls, not the slightest sign of its mass spectrum could be obtained The substance seemed hopeless, so I proceeded to my next investigation, which was an attempt to get the mass spectrum of gold by volatilising its chloride This compound is unstable and, as the presence of halogens had on some previous occasions brought out the lines of other bodies in a remarkable way, it seemed just worth while to volatilise it in the discharge tube before the rhenium oxide deposit had been removed from the walls This procedure was successful beyond all expectation Although no lines of gold were visible the doublet lines of rhenium appeared in great intensity and in addition were repeated 16, 32, and 48 units higher as ReO, ReO_2, and ReO_3, so giving unusually convincing evidence of its constitution

Rhenium consists of two isotopes, 185, 187, as was expected from the general rule that complex elements of odd atomic number (above 9) consist of two odd mass numbers two units apart, but it is the first element analysed in which the heavier isotope is the more abundant The ratio of this abundance was estimated photometrically by analogy with the mercury lines to be 1 62 1 The position of the line 203 due to $Re^{187}O$ in the mercury group was used to determine its packing fraction, which is -1 ± 2, the same as that of osmium From these provisional values the atomic weight on the chemical scale works out at $186\,22 \pm 0\,07$, in good agreement with Hönigschmid's latest value of 186 31 The strongest isotope of rhenium is isobaric with the weakest of osmium

The Behaviour of Antiknocks

IT is generally agreed that it is the metallic radicle of an organometallic antiknock compound that is mainly responsible for the delaying of the oxidation of a combustible mixture That the metal atom is in an oxidised state before it becomes effective, was an inference made on the basis of many different experimental facts, for example, the behaviour of potassium vapour,[1] but it has not been proved directly We have recently been able to show that a small quantity of lead tetraethyl vapour, when let into an evacuated vessel heated to 265° C into which a charge of pentane vapour and oxygen is afterwards introduced, will not affect the course of the combustion to any great extent and may even accelerate it, but that if some oxygen is let into the vessel before the lead tetraethyl vapour, and then this followed by the bulk of the charge, the combustion is invariably strongly inhibited These experiments provide direct evidence that the lead must first be oxidised before it is effective as an inhibitor It is possible that the accelerating effect is due to the C_2H_5 radicles which help to start reaction chains, but that has yet to be proven

Pasteurised and Raw Milk

IN NATURE of Mar 21, p 466 an abstract appears of a report issued by the Department of Health for Scotland on "Milk Tests in Lanarkshire Schools", by G Leighton and P L McKinlay In this experiment, nearly ten thousand school children received a supplementary ration of three quarters pint of milk daily for about four months Two important tables from the report showing the average increases in height and weight of the children, divided into 14 groups by age and sex, are reproduced

The special point to which we wish to direct attention concerns the apparent contrast in the effects of pasteurised with that of raw milk About half the children receiving milk consumed it raw, while the other half were supplied with milk from the same source which had been pasteurised It is somewhat unfortunate, however, that the recipients in the same school were never so divided, the whole of the milk supplied to any one school being either raw or pasteurised In the absence of the records from the separate schools it is impossible altogether to eliminate the doubt which this choice of method introduces nevertheless, the report concludes with the statement (p 20)

"In so far as the conditions of this investigation are concerned the effects of raw and pasteurised milk on growth in weight and height are so far as we can judge, equal"

The importance of such a conclusion, if well established is manifest It is however open to some question, for Table 12 printed on the same page, shows that of the 14 groups (by age and sex), pasteurised milk gave a greater increase in height in only 2 groups, the increases were equal in 1 group, while in 11 groups the raw milk gave the greater increase If we may regard these as 14 independent experiments, the difference from expectation on the hypothesis that raw and pasteurised milk have the same effects, is such as would only occur once in about ninety trials, and it seems evident that the conclusion should have been that the *growth response in height to raw milk is significantly greater than that to pasteurised milk*

In order to examine the magnitude of the difference

we have calculated from Tables 6 and 7 of the Report the average increments in the control, raw milk and pasteurised milk groups, weighting the averages given according to the total numbers of boys and girls in each group In this way we find an average increase in height and weight, standardised for age, for the whole group of children observed From the average increase, the excess ascribable to milk feeding is obtained by subtraction, and the relative value of pasteurised as a percentage of the value of raw milk, as measured by increase in growth, is calculated from the two differences

AVERAGE INCREASES IN WEIGHT IN OUNCES

	Boys		
	Control	Raw Milk	Pasteurised
Increase	10 041	13 780	12 507
Excess over control		3 739	2 466
Value per cent		100 0	66 0

	Girls		
	Control	Raw Milk	Pasteurised
Increase	9 755	14 315	13 907
Excess over control		4 560	4 152
Value per cent		100 0	91 1

In weight the average increment ascribable to the consumption of about 10 gallons of milk is a little more than 4 ounces, being a little more for girls than for boys In both sexes the pasteurised milk gives a lower return, the increment ratios being 66 0 per cent in the case of boys, and 91 1 per cent in the case of girls In respect of growth in height the contrast is even more striking

AVERAGE INCREASES IN HEIGHT IN INCHES

	Boys		
	Control	Raw Milk	Pasteurised
Increase	0 7274	0 8145	0 7707
Excess over control		0 0871	0 0433
Value per cent		100 0	49 8

	Girls		
	Control	Raw Milk	Pasteurised
Increase	0 7300	0 8140	0 7889
Excess over control		0 0840	0 0589
Value per cent		100 0	70 1

Measured by its effect in increasing growth in height, pasteurised milk appears from these data to have only half the value of raw milk in the case of boys, and about 70 per cent of the value in the case of girls

These results are put on record to avoid the danger that, from a superficial examination of the report, the conclusion should be drawn that this extensive experiment demonstrates the equivalence of pasteurised and raw milk In reality the reverse is the case, and the very marked difference in response to two materials, which in their gross nutritional contents are so closely equivalent, raises a problem of very great interest, which can probably only be cleared up by more deliberate experimentation The contrast between the response to pasteurised milk and that to raw milk is of value also in interpreting the difference between the milk-fed and the control children, for it would evidently be extremely rash to draw from the experimental results the 'natural' conclusion, that the increases induced by milk feeding indicate that the Lanarkshire children are, in their normal diet, inadequately supplied with such nutrients as fat, protein, or sugar, which are contained equally by the raw and by the pasteurised milk

Capture of Electrons from Mercury Atoms by Positive Ions of Helium.

IN a recent paper[1] we gave an account of some experiments on the determination of the mobility of ions in helium gas at a pressure of 360 mm of mercury We found that the mobility of the positive ions decreased when small traces of other impurities were introduced into the apparatus, and we interpreted the results as due to an 'exchange' phenomenon similar to that observed by Kallmann and Rosen in the case of high speed positive ions On this view, when a helium ion 'collides' with an impurity molecule there is a certain probability that an electron will be captured from the impurity by the ion The impurity ion so formed will not lose its charge in collisions with other helium atoms, because the ionisation potential of helium is greater than that of any impurity and the speed of the ions in our experiment is much too small to supply the energy required for the transition For this reason, a very small concentration of impurity is sufficient to change completely the rate at which the positive charge is carried through the gas

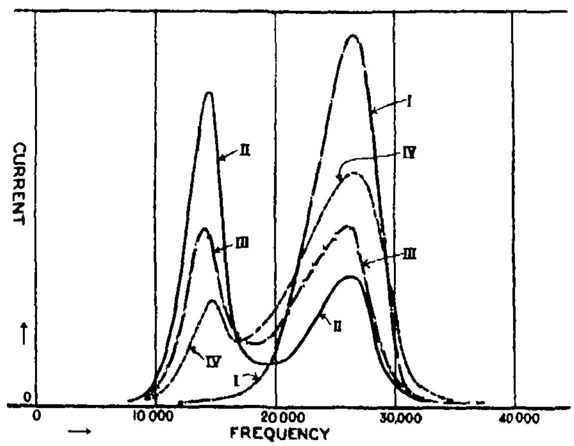

FIG 1

In our first experiments we had not sufficient control of the purity of the gas to identify the impurities which gave rise to ions of smaller mobility We have now made experiments in a new apparatus in helium at 20 mm pressure and have obtained a definite example of the exchange phenomenon from helium to mercury

In our method of measuring the mobility of ions in gases, a peak is obtained in a current frequency curve for each type of ion present (Fig 1). Curve I shows the curve which we obtained for positive ions in pure helium in a baked-out apparatus, mercury vapour being excluded by liquid air traps. On

admitting mercury vapour to a concentration of one part in 30,000 of helium, Curve II was obtained. It will be seen that instead of the original single peak, two peaks are now present. The peak at the higher frequency coincides in position with the original single helium peak and is due to helium ions which have traversed the apparatus without losing their charge by interchange to mercury. The peak at the lower frequency indicates the presence of mercury positive ions which have been formed by electron capture from helium ions. On freezing out the mercury with liquid air, Curve I was again obtained. Curves III and IV are for successively smaller concentrations of mercury and show corresponding reductions in the number of mercury ions. Though some of the mercury ions may possibly arise from collisions of mercury atoms with metastable atoms of helium in the neighbourhood of the primary source of ionisation, the greater number at least must be due to electron exchange. This was shown by giving the ions a longer life before entering the analysing part of the apparatus; the relative number of mercury ions was then found to increase, roughly linearly with the age of the ions.

These results not only give an illustration of electron capture but also afford a method of determining the mobility of positive ions, other than those of helium, moving in helium gas. Thus the ratio of the mobility of a mercury positive ion in helium to that of a helium ion in helium is 0.55.

Also, by repeating the measurements with known minute concentrations of other gases, we may hope to determine the target area for electron capture presented by their molecules to helium ions of very slow speed. Experiments on these lines with hydrogen, nitrogen, and other gases as impurities are now in progress.

Spectra of the Helium Glow Discharge

FOR some time past we have been investigating the cold cathode glow discharge in helium with probe wires, for approximately 'normal' conditions at a pressure of about 1 mm. of mercury. The work with cathode falls in potential less than 100 volts is still incomplete, but two cases in which we have been able to correlate the spectrum with the electrical data are of some interest.

The first concerns the distribution of intensity in the arc spectrum (He I). This is well illustrated by the behaviour of the lines at 5016 A. and 4713 A., the latter being very feeble compared with the former in the negative glow, whilst the two are of comparable intensity in the anode glow. From the current voltage characteristics of the probe wires, we find that the distribution of velocities amongst the electrons is not Maxwellian in the negative glow, but can be represented fairly closely by the superposition of several Maxwellian groups; in a typical instance, the temperatures of these were 300,000°, 54,000°, and 4900°, and the concentrations 8×10^{8}, 5×10^{7}, and 1×10^{9} per c.c. respectively. In the anode glow, in another instance, a single group was present, with a temperature of 60,000°. From these numbers, we can calculate the relative intensities to be expected for the lines, from data given by Elenbaas [1] for their intensities when they are excited by electrons of definite speeds. It can be shown in this way that λ5016 would be expected to be about 17 times as strong as λ4713 in the negative glow, but only 4.5 times as strong in the anode glow, in reasonable agreement with our visual estimates. Our previous conclusion [2] that electrons with anything like the full cathode voltage are not present in at all large numbers under these conditions also receives confirmation from the extremely feeble intensity of the spark line λ4686.

The second observation is that Seeliger and Mierdel's suggestion that metastable atoms are rapidly destroyed by slow electrons [3] finds support from our measurements if at least one of the two atoms which go to the formation of a molecule He_2 is initially in such a state. It is found, as Seeliger and Mierdel supposed, that helium bands appear only in those parts of the discharge where there is a considerable concentration of relatively fast electrons (with energy greater than 20 electron volts) and a *small* concentration of slow electrons (with energy less than about 1 electron volt). The kinetics of the processes involved are not clear, but the atomic process coming into play in the destruction of metastable atoms by slow electrons is possibly the converse of that which causes the sharp maximum in their excitation functions.

Isostasy

IN scientific literature of to-day dealing with geophysical matters one frequently meets assertions that the hypothesis of isostasy is universally established. Prof. Heiskanen begins a recent article,[1] "In recent years geodesists, geophysicists, and geologists have studied extensively isostatic compensation and it can be considered as a proved fact that isostatic compensation prevails, at least in North America (Hayford, Bowie), in India (Pratt, Airy, Burrard, Crosthwait), etc." I consider this statement far from true as regards India. Pratt and Airy, whose work is published in the *Phil. Trans. Roy. Soc.* (1854–59), had only three values of the meridian value of the deflection of the vertical on which to base their studies. Pratt *suggested* the idea of *mountain* compensation; but he did not completely satisfy the observational points. Burrard in 1901 [2] did not agree with Pratt's conclusion; later on, however, in 1918,[3] by extending the scope of Hayford's isostatic hypothesis to include compensation of density anomalies, he was able to satisfy the observational data then existent in the Himalaya and neighbouring regions by attributing appropriate depth to such anomalies. Crosthwait in 1912 [4] wrote "Speaking generally, it would appear that isostatic conditions are much more nearly realised in America than in India." He had made the necessary calculations for the Hayford deflection at 102 latitude stations and 18 longitude stations distributed over India.

My recollection of the opinion held in 1912 in the Survey of India was that a state of isostasy did not exist in India. Later, in 1918, Burrard was inclined to think otherwise.

Since 1918, however, the results of observations at many more deflection stations have been considered (229 latitude, 19 longitude—227 azimuth). We have studied these intensively during recent years. Meantime the number of pendulum stations has increased from 118 in 1918 to 205 in 1930. The form of the geoid as traced from the value of deflection has been

supported by its accord with the pendulum anomalies The conclusions drawn are as follows [5]

(a) That in peninsular India in general, isostatic compensation definitely does not prevail An area of 100,000 sq miles in the Gangetic Plain shows an anomaly ranging from 1000 to 6700 feet equivalent surface rock, while north of Nagpur is an area of 50,000 sq miles with anomaly ranging from - 1000 to - 3700 feet of rock

(b) That in Himalayan regions there is some measure of compensation, but the total area in which adequate observations have been made is small

It is entirely wrong then to quote India as a region supporting the hypothesis of Hayford isostasy Isostasy *may* prevail in the Himalaya, as Pratt suggested, but it does not prevail over the remaining portion of India

Origin of Cosmic Radiation

THE frequency ν of radiation can be deduced from its absorption μ by means of the well known formula of Klein and Nishina,[1] which can be put in the form

$$\mu = \frac{2\pi N e^4}{m^2 c^4} f\left(\frac{h\nu}{mc^2}\right)$$

This gives frequencies which agree well with experiment up to the frequencies of the hardest γ rays, beyond this it is impossible to test it

The formula supposes absorption to result entirely from scattering by free electrons (N per cubic cm) In dealing with γ radiation, all extra nuclear electrons are treated as free, since (in the language of classical theory) their period of oscillation is long compared with the period of the incident radiation The nuclear electrons and protons have 'periods of oscillation' comparable with those of γ radiation and so must not be treated as free, except when the incident radiation is of far shorter period than γ radiation Cosmic radiation comes within this latter category, whence it appears probable that in deducing the wave length of cosmic radiation by the Klein Nishina formula N ought to refer to all electrons, nuclear as well as extra nuclear, and not merely to the latter A second term ought also to be added to represent scattering by protons, but calculation shows that this is entirely insignificant The effect of taking the nuclear electrons into account is to double, or more than double, the absorbing power of all atoms except hydrogen It increases the absorbing power of water for cosmic radiation to eighty per cent above the value usually calculated

The following table shows the absorption (per metre of water) calculated for the radiation produced by the synthesis of iron, and by the annihilation of 1, 2, and 4 protons and their accompanying electrons

Process	$\frac{h\nu}{mc^2}$	Calculated μ Extra nuclear electrons	Calculated μ All electrons	Observed μ (Regener)
26 H → Fe	876	0 076	0 136	
+ − → O	1845	0 039	0 071	0 073
+ + − − → O	3690	0 021	0 038	
+ + + + / − − − − → O	7380	0 011	0 020	0 020

The last column gives the true absorption of the two most penetrating constituents of cosmic radiation, as analysed by Regener [2] The agreement with the figures in the preceding column is probably well within errors of observation Although the problem is beset by every kind of uncertainty, this agreement at least suggests that the most penetrating constituent so far observed in cosmic radiation may originate in the annihilation of an α particle and its two neutralising electrons (the components of a helium atom), while the next softer constituent may originate in the annihilation of a proton and its one neutralising electron (the components of a hydrogen atom) Such an interpretation leaves no room for radiation originating in the simultaneous annihilation of two protons and two electrons which would result in a unit decrease in atomic number Although this may seem surprising at first it accords well with the marked differentiation between elements of odd and even atomic numbers, with the fact that radioactive atoms eject α particles but never protons, with the fact that no atom of atomic weight 2 is known, and also, I think, with the general spirit of nuclear physics

These two constituents appear to be far too hard to be produced by the synthesis of iron, while the synthesis of heavier elements would seem to be ruled out by their rarity in the universe If the annihilation of matter is the true origin of the two hardest constituents of the cosmic radiation, it would seem likely that these and these alone form the fundamental radiation and that all other constituents represent mere softened or degraded forms of these No calculation I have ever been able to make seems at all friendly to Millikan's suggestion [3] that the hardest radiation of all has its origin in the synthesis of iron

Chemistry of Vitamin B_2

A CHEMICAL study of vitamin B_2 in a cold aqueous extract of commercial liver extract (Eli Lilly, No 343) has been made This solution is very rich in vitamin B_2, being effective in producing good growth in young rats on a B_2 deficient diet, in a daily dose representing 40 60 mgm of the original liver extract

Picric acid and benzoyl chloride do not precipitate the vitamin, nor is it precipitated or destroyed by nitrous acid It is not precipitated by flavianic acid Neutral lead acetate partially precipitates the active material both at pH 4 6 and 7, while litharge does not precipitate it at all Silver nitrate precipitates the bulk of the vitamin Baryta does not precipitate it either in an aqueous solution or in a medium of 50 per cent alcohol 'Norite' charcoal adsorbs the factor at the natural pH of the aqueous liver extract (pH 4 6), which, however, could not be eluted by acid, alkaline or neutral water alcohol mixtures, or by a dilute solution of saponin Three extractions with 30 per cent propyl alcohol appeared to extract it partially with a considerable loss of activity Treatment with phosphotungstic acid gives an inactive precipitate and a filtrate with a small degree of activity A combination of the two is equally unsatisfactory Esterification with ethyl alcohol leaves the bulk of the activity in the non esterified portion, the ester itself being almost wholly devoid of activity Trypsin has no effect on the vitamin

On the basis of the present evidence it appears that, if the vitamin is a single chemical entity, it is probably not a base, an acid, or a peptide, but a neutral

substance Preliminary experiments on the electro dialysis of vitamin B_2, carried out with Mr T W Birch, also appear to support this conclusion These fractionation experiments have given the general impression that vitamin B_2 is fairly readily adsorbed by neutral precipitates Thus, the partial precipitation by lead acetate and also by silver nitrate is probably merely due to the adsorption of the vitamin on to the precipitates formed

Though the liver extract is potent in both vitamin B_2 and the factor specific for pernicious anæmia they appear to be different from evidence of the methods of their fractionation and also on other grounds

The stability of vitamin B_2 to heating under pressure in an alkaline medium shows curious discrepancies Commercial liver concentrate and commercial yeast extract ('marmite') are both fairly stable to autoclaving at pH 9 at 124° C, while aqueous extracts made from brewer's yeast, fresh ox liver, and ox muscle are markedly unstable under the same conditions The stability appears to be connected with the presence of certain protective materials in a given fraction

The vitamin is stable to sulphur dioxide hydrogen peroxide, and ozone

Embryology and Evolution

DR A PINEY, in his letter to NATURE of Feb 28 accuses me of reviving a dormant form of vitalism but with the deification of entelechy I certainly have no association He says The sterility of vitalistic hypotheses in the past leads one to doubt their fertility in the future", but the fecundity of alternative hypotheses is not conspicuous

Dr Piney defines science *in modo et forma* with masterly assurance that the man of science has no concern with what lies outside his conceptual schemes, yet the actual instability of such schemes indicates that the real motive of the scientific worker is the attempt to discover what Dr Piney himself admits may be of the greatest importance

As biologists, whether we incline to the belief that the living cell is something self contained and perfectly unique in the universe, or whether we suspect that it, in common with the rest of matter, is subject to obscure external forces, our confession in regard to the control of vital processes, so far, is one of ignorance But those of us who feel that the living cell is a machine in miniature, the very life of which depends, as a familiar fact, upon its reception of electromagnetic radiations of the order 8000 to 4×10^6 A, may perhaps be pardoned for suspecting that the protoplasmic cogs are driven by external forces, even though we profess no adherence to the views of the great Nicholas of Cusa

High-flying Egrets at Night

ASTRONOMICAL and ornithological readers of NATURE may be interested to hear of a somewhat extraordinary experience I had rather early in the morning of Feb 16 while sweeping for comets About 12 30 A M I was suddenly startled to see in the field of view of my 7¼ inch reflector, using an eyepiece giving about 35 power, about twelve to fifteen large golden coloured objects, like third magnitude stars much out of focus, and thus enlarged, crossing the field at a fair pace At first I wondered what it could be It was as if a star cluster like the Pleiades had suddenly taken to flight I soon recognised as I followed the objects in the telescope that they were a flight of the little white egrets, passing a little more than a mile away, and so high up that the electric lights of the city lit up the under side of their wings, giving them a golden colour like stars I followed them for about two minutes first in the reflector and then in the finder, until they got out of my reach towards the west When first I saw them they were perhaps a little to the east of the Southern Cross, and about the same altitude, say 45°–50° They travelled west and passed 4° or 5° below Canopus, and then I lost them, as they got too far west for my balcony

These egrets are often seen in these parts following cattle and eating the flies in their track or on their bodies It would be interesting to know if anyone has seen such a thing at night before They were flying in a wedge shape, and I could see the motion of their wings probably about one mile high and one mile away Of course, in the daytime birds have been seen crossing the sun's disc, but this was midnight

Fine Structure in the Mercury Singlet Terms: A Correction

I WISH to direct attention to an error in the particulars I have recently given [1] of the fine structure of the line λ6234 ($7\,^1S_0 - 9\,^1P_1$) in mercury The positions of the components g and f given as – 0 406 and – 0 696 cm^{-1}, are actually 0 306 and – 0 544 The diagram in Fig 2 requires a corresponding emendation The corrected value 306 for the interval bf in $7\,^1S_0$ $9\,^1P_1$ now agrees reasonably well with the interval 308 (be) of λ5676 ($7\,^3S_1 - 9\,^1P_1$) and its previous allocation to the $9\,^1P_1$ level is thus confirmed Further, the intervals 31, 121, 156 which occur in the $9\,^1P_1$ term are now seen to be consecutive since their sum 308 is established as a real difference The main conclusions reached in the paper are not affected by the error

The Theory of Geological Thermal Cycles

DR J H J POOLE's opening paragraph (NATURE, April 4 p 518) suggests that in my first criticism of Prof Joly's theory I did not consider the possible effects of fusion in the production of periodicity On the contrary, the main topic of the paper was to discuss whether fusion could have such an effect, and none was found

I need scarcely say that I do not share Dr Poole's doubt as to whether a fluid, with internal generation of heat, would maintain the adiabatic gradient of temperature There is abundant theoretical reason for this, and it is in accordance with meteorological experience

Canadian Hydro-Electric Power Development during 1930.

By Dr BRYSSON CUNNINGHAM

THE remarkable progress which, during recent years, has characterised the development of natural sources of water power in Canada for the generation of electricity and other industrial uses continues at an unrelaxed pace, and the two annual reports [1] recently issued by the Canadian Government contain a record of activities during 1930 which is quite up to the standard of preceding years. The present rate of development in round figures is 400,000 additional horse power a year, and as the aggregate has grown from $3\frac{1}{2}$ million horse power in January 1924 to a little more than 6 million horse power in January 1931, it is obvious that, roughly, the rate has now been maintained for a period of seven years. Taking the comparative value of coal fuel for power generating purposes at $5\frac{1}{2}$ tons per annum per horse power (the most recent estimate), it can be inferred that Canada is progressively supplementing her extremely meagre resources in mineral fuel by the equivalent of a supply of about $2\frac{1}{4}$ million tons of coal per annum. Moreover, as compared with coal, water power energy has the advantage of perpetuity, for, once installed, the turbines may continue to function for an indefinite period, in contradistinction to the inevitable, though gradual, exhaustion of fuel used in thermal stations.

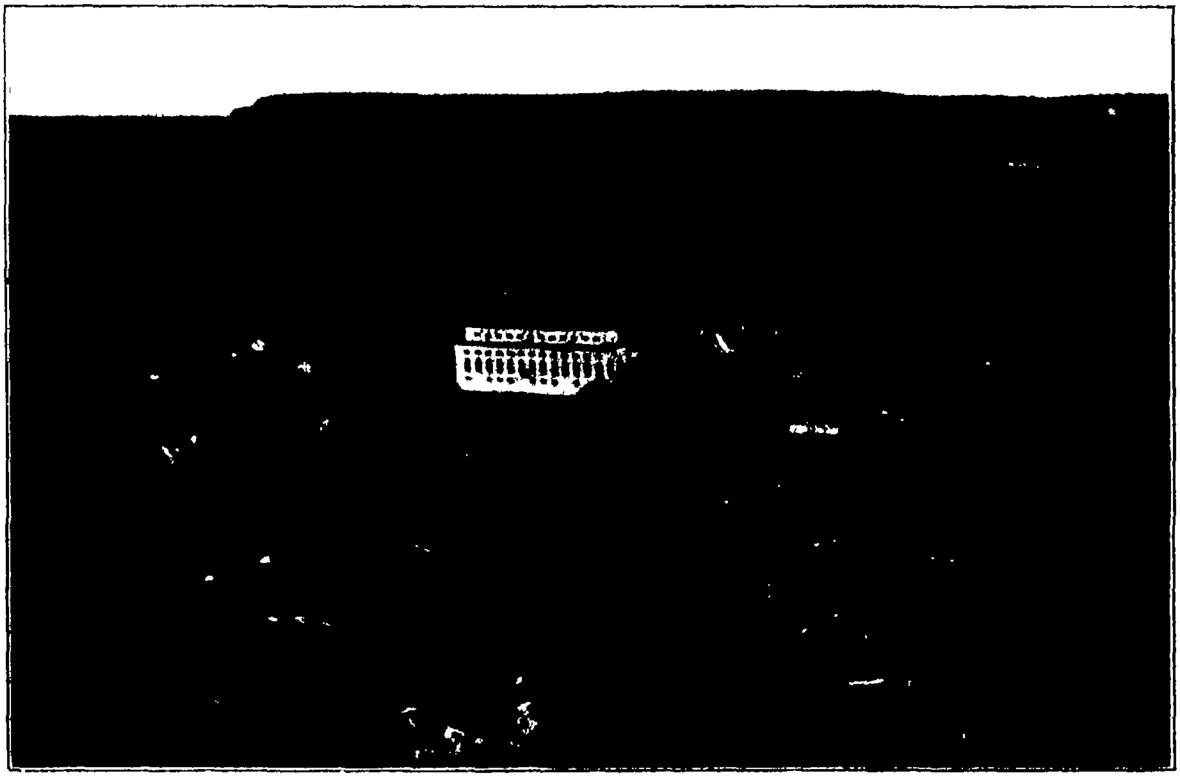

FIG 1 —Cameron Falls development, Nipigon River, Ontario (75,000 horse power) of the Hydro-Electric Power Commission of Ontario (By courtesy of the High Commissioner of Canada.)

The precise figures of available and developed water power, as ascertained to Jan 1 last, are set out in the table on p 597. They may be instructively compared with the corresponding statistics at Jan 1, 1930, which were published in NATURE on May 31 last.

It will be noted that there has been no further revision of the total available horse power, which still stands at 33,617,500 (ordinary six months' flow), although the report indicates that, in some of the more remote and less explored districts, the figures must be accepted as provisional and subject to expansion as the work of surveying and tabulation proceeds. Moreover, the present estimates are of a decidedly conservative character, as may be gauged from the fact that actual development of existing sites has produced power some 30 per cent in excess of the calculated maximum. Hence it is fairly safe to say that the total water horse power assets of Canada are of the order of 43 or 44 millions. According to information gathered from reports of the United States Geological Survey, this compares roughly with about 80 millions in the United States. The water power resources of Great Britain on this scale are insignificant: perhaps a million, or, at the outside, a million and a half.

As regards actually developed power, the aggregate increase throughout the Dominion is 397,850

horse power, of which the bulk has been realised in the provinces of Ontario and Quebec, though notable progress has also been made in British Columbia, Saskatchewan, and New Brunswick Very little change has taken place in Nova Scotia, and the other four provinces remain stationary

The province of Ontario heads the list of increments with 136,000 horse power The most important item in this total is a tenth unit of 58,000 horse power added to the Queenston station at Niagara Falls, bringing the aggregate capacity of the station, which is the largest in Canada, up to the imposing figure of 560,000 horse power Almost as large an increment is the recently completed 54,000 horse power development on the Nipigon River at Alexander Landing, a short distance below the 75,000 horse power installation at Cameron Falls (Fig 1) The Hydro Electric Power Commission of Ontario has at present in hand, in conjunction with the Ottawa Valley Power Company, the development of Chats Falls, on the Ottawa River, at a site which lies astride the Ontario Quebec boundary, where, forming part of a project for 280,000 horse power, eight units, aggregating 224,000, horse power, are being installed Other important schemes have materialised at the Upper Notch station on the Montreal River, belonging to the Canada Northern Power Corporation, at the Canyon on the lower Abitibi River, under the Ontario Power Service Corporation, and at High Falls, Michipicoten River, for the Algoma District Power Company

The Province of Quebec, with an increment of 122,700 horse power during the year, is a close second to Ontario The additions have been contributed by five organisations The MacLaren-Quebec Power Company has installed 90,000 horse power, out of a proposed 120,000 horse power development, on the Lievre River (Fig 2), and contemplates the construction of a second 120,000 horse power station near the junction of that river with the River Ottawa The Cedar Rapids Reservoir of 25 thousand million cubic feet capacity has also been brought into commission The Shawinigan Water and Power Company has added a 25,000 horse power unit to the plant at Grand'mère and is now supplementing the station at La Gabelle with a 30,000 horse power unit, both on the St Maurice River, farther up which an initial installation of 160,000 horse power is in hand at Rapide Blanc Smaller installations have been effected by the Lower St Lawrence Power Company and two other concerns

The Province of Quebec will receive a considerable augmentation of power in the near future when the undertakings of the Beauharnois Power Corporation on the St Lawrence River (200,000 horse power and ultimately 500,000 horse power), the Alcoa Power Company on the Saguenay River (260,000 horse power), and the joint development, above referred to, of the Ottawa Valley Power Company and the Hydro-Electric Power Commission of Ontario, on the Ottawa River, are completed The Saguenay River project at Chute-à-Caron is actually at the point of completion The

FIG 2 —High Falls development, Lievre River, Quebec (90 000 horse power) of the MacLaren Quebec Power Co (By courtesy of the High Commissioner of Canada)

AVAILABLE AND DEVELOPED WATER POWER IN CANADA JAN 1, 1931

Province	Available 24 hour Power at 80 per cent Efficiency		Turbine Installation (h p)
	At Ordinary Minimum Flow (h p)	At Ordinary Six Months Flow (h p)	
British Columbia	1,931,000	5,103,500	630,792
Alberta	390,000	1,049,500	70,532
Saskatchewan	542,000	1,082,000	42,035
Manitoba	3,309,000	5,344,500	311,925
Ontario	5,330,000	6,940,000	2,088,055
Quebec	8,459,000	13,064,000	2,718,130
New Brunswick	68,600	169,100	133,681
Nova Scotia	20,800	128,300	114,224
Prince Edward Island	3,000	5,300	2,439
Yukon and N W Territory	294,000	731,000	13,199
Totals	20,347,400	33,617,200	6,125,012

Note —' Ordinary Minimum Flow ' is based on the averages of the flows for the lowest two periods of seven consecutive days in each year, over the period for which records are available Ordinary Six Months Flow is based on the continuous power indicated by the flow of the stream for six months in the year The actual method to determine this flow is to arrange the months of each year according to the day of the lowest flow in each The lowest of the six high months is taken as the basic month The average flow of the lowest seven consecutive days in this month determines the ordinary six months' flow for that year The average of such figures for all years in the period for which data are available is the ordinary six months flow used in the calculation

Beauharnois project was referred to in NATURE of Dec 14, 1929, p 930, at the time of the inauguration of constructional operations by His Excellency the Governor General It is a most important undertaking, comprising an overland canal from the St Lawrence River, 15 miles in length, 600 ft wide, and 27 ft deep The canal will extend from its intake at Lake St Francis to a power house and locks at Beauharnois on Lake St Louis, where a direct fall of 83 ft will be obtained

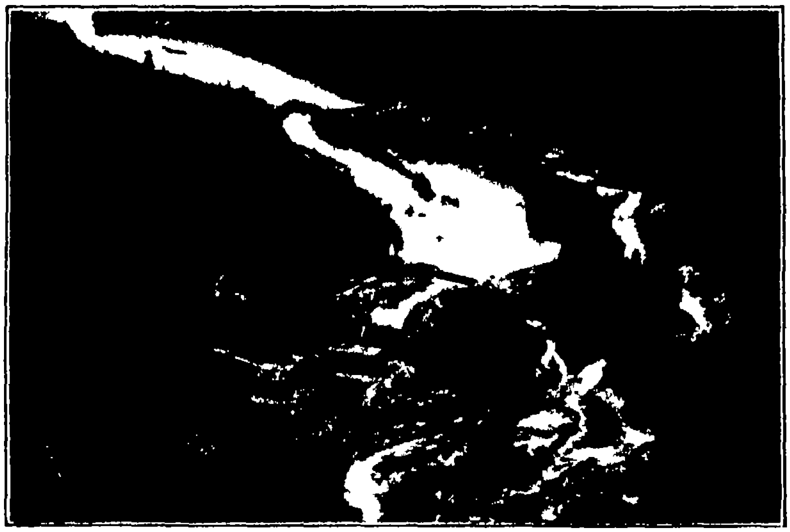

Fig 3 Aroostook Falls development Aroostook River, New Brunswick (11,400 horse power), of the Maine and New Brunswick Electric Power Co, Ltd (By courtesy of the High Commissioner of Canada)

The financial commitments in schemes of this magnitude are necessarily of a very high order In the aggregate, it is computed that during the past year a sum of no less than 80 million dollars (say £16,000,000) has been expended on programmes of construction at the various centres, and it is estimated that a further outlay of 300 million dollars (£60,000,000) will be incurred during the next two or three years More than 11,000 men are at present employed in actual constructional work *in situ*, in addition to a large army of operatives engaged at factories and elsewhere in producing material and equipments

There are many features of interest among the lesser undertakings, but space does not permit of reference to them A picturesque view of a relatively minor development in New Brunswick is shown in Fig 3

A substantial part of the Report on the Water Power Resources of Canada is devoted to a detailed account of the various ways in which the developed power is utilised The overwhelming bulk (85 1 per cent) is produced at central electric stations for general distribution for industrial, municipal, commercial, domestic, and agricultural use A much smaller amount (9 5 per cent) is directly applied to the power plants of pulp and paper mills, but this is scarcely a true index of the demands of this industry, by far the most important in Canada, since large quantities of electricity are purchased *en bloc* from the central stations The balance of 5 4 per cent is absorbed in general industrial undertakings, such as mines and mineral reduction works, electro chemical plants, saw and timber mills, machine shops pumping plants, and for electric railway operation The total water power installed at the present date works out at 617 horse power per 1000 of population, and places Canada in an outstanding position *per capita* among water-power using countries The capital so far invested is estimated almost to reach the startling figure of 1,390,000,000 dollars, or nearly £280,000,000

[1] Report No 1462 Hydro electric Progress in Canada in 1930 Report No 1474 Water Power Resources of Canada (Ottawa Department of the Interior, Canada Dominion Water Power and Hydrometric Bureau)

Work of the Medical Research Council

THE Report of the Medical Research Council for 1929–30 * indicates as usual the wide range of the researches carried out by members of its staff or by other investigators, assisted by grants The value of the funds available has been enhanced by the collaboration of various public bodies with the Council in specific schemes of research and by the facilities provided for investigations by university and other laboratories During the year, Sir Frederick Gowland Hopkins and Sir Charles Martin retired from the Council, and their places were filled by the appointment of Sir Charles Sherrington and Dr J A Arkwright

* Committee of the Privy Council for Medical Research Report of the Medical Research Council for the year 1929–30 (London H M Stationery Office 1931) Pp 138 2s 6d net

Clinical Research and Experimental Medicine

During the year, University College, London, established within its Hospital a Department of Clinical Research Sir Thomas Lewis was appointed as the first physician in charge of the Department on his resignation as a member of the ordinary staff of the Hospital He will continue, as before, to give whole time service to the Medical Research Council At Leeds, Birmingham, and Aberdeen, steps are being taken to provide full-time positions for clinical research At Aberdeen also, the professor of pharmacology is to be given charge of beds within the new Royal Infirmary, thus reproducing the conditions at

Sheffield, where Prof E Mellanby is both professor of pharmacology and a physician to the Royal Infirmary

Sir Thomas Lewis and his colleagues have studied Raynaud's disease they have shown that the malady is due, as Raynaud thought, to arterial spasm, and that the abnormal element in the reaction to cold is a direct reaction, due to a peculiar condition of the vessel wall, and is not the result of a reflex through the vasomotor nerves In further analysis of the reaction of the body to cold, they have shown that after a finger has been immersed in cold water for 5 10 min , a vasodilatation occurs which is due to an axon reflex in the sensory nerves This mechanism plays an important part in protecting exposed areas from excessive cooling and subsequent injury

BIOLOGICAL STANDARDISATION

The Council plays an important part in the development of methods of precision for the measurement of therapeutic agents which cannot be estimated by direct chemical means, in the preparation of standards of reference for these assays, and in the administration of the Therapeutic Substances Act The full value of this work is only attainable by international agreement, for which the League of Nations has set up a permanent International Commission on Biological Standards under the chairmanship of Dr Madsen Dr H H Dale, director of the National Institute for Medical Research, is the British representative on this Commission

The issues of samples of standards to licensees under the Therapeutic Substances Act numbered 190 500 samples of different substances were tested for the authority administering the Act A considerable number of these were samples of "sterilized surgical catgut", which was added to the schedule of therapeutic substances during the year A dried antiserum for, and suitable toxin of, *B Welchii* have been prepared and are available for issue whenever an international standard for the former has been defined

For the past sixteen years, all the toxicity and potency tests of samples of novarsenobenzene and sulpharsenobenzene have been carried out by members of the staff of the Institute The exact terms of the test can now be precisely defined and standards of toxicity and potency have been laid down by international agreement It was therefore found possible during the year to direct British manufacturers to perform the biological tests for themselves, so that the Institute will gain resources of time and material for progressive research in chemotherapy

A standard for vitamin D in the form of a solution of irradiated ergosterol was also made available during the year and supplied to twenty eight institutions in Great Britain and in eight other countries

INSULIN

Except for a few months immediately after its discovery, the supply of insulin has always exceeded the demand in Great Britain and has provided a growing export trade At the same time, the home demand has continually increased, for example, the consumption in 1930 was four times greater than in 1925 But even the present consumption corresponds with much less than the present number of diabetic patients in Great Britain, so far as that can be estimated Again, the proved benefit of insulin in the individual case is not reflected in the death-rates for diabetes as a whole, which have remained fairly steady since 1922 Both these facts suggest that insulin is being inadequately utilised

Analysis of the death rates, however, shows that at the earlier ages there has been a reduction since the introduction of insulin thus the mortality of males less than 55 years of age has been reduced by 37 per cent and of females by 21 per cent since 1923 Above 55 years of age, the death rate for males neutralises the earlier decrease and for females actually outweighs it The increase is evidently dietetic, since the mortality at these higher ages was greatly reduced during the War and it is in this type of case that insulin treatment is least frequently used

NUTRITION AND VITAMINS

The Council has arranged a trial, among Royal Air Force personnel, of the value of regular administration of vitamin A in the prevention of colds or other ailments during the winter months, and with the co operation of the medical staff of the London County Council, of its usefulness in the treatment of infective middle ear disease after scarlet fever, and in the prevention of dangerous sequelæ after the common infective fevers Prof E Mellanby and his colleagues have continued their work on the anti infective action of vitamin A it appears to improve the chances of recovery in puerperal fever, and also, administered prophylactically, to reduce the incidence and the severity of any infections which may develop They have also found that cereals, especially the germ, will produce degeneration in the spinal cord when the body is deprived of vitamin A, administration of the vitamin will bring about rapid improvement of function Vitamin A also prevents the neurological changes found in 'ergotism'

The pure substance carotene has both the growth promoting and anti infective properties of vitamin A, although chemically it is an entirely different compound Moore has shown that when carotene is given to rats, large quantities of vitamin A, detected by colorimetric and spectroscopic tests, can be found in their livers, indicating that carotene is converted to vitamin A in the body (see *Biochem Jour*, vol 23, p 1267, 1929 vol 24, p 692, 1930)

Chemical studies of vitamin D have been continued by Bourdillon and Webster and their colleagues The mixed products of the irradiation of ergosterol have been fractionated by distillation in a high vacuum Partial destruction occurs, but a fraction of high activity can be obtained and,

from this, active crystalline products, but the potency is not high enough to justify the supposition that the vitamin is present in pure form Evidence has also been obtained that at least one other substance is formed as a primary irradiation product of ergosterol with the vitamin D

Vitamin deficiencies have been found to have effects upon the heart Carter and Drury found that bradycardia and heart block occurred in pigeons fed on polished rice Drury, Harris, and Maudsley observed a bradycardia in rats fed on diets deficient in vitamin B, which differed from the former type in being of sinus origin and not due to vagal influence

Mackay has found that anæmia is common in artificially fed, and to a less extent in breast-fed, infants, and is due to a deficiency of iron The anæmia diminishes resistance to infection and retards growth It can be prevented, and the morbidity rate simultaneously reduced, by administering a suitable form of iron salt

Miss Durham has now completed a prolonged experiment upon the effects of alcohol on the fertility of guinea pigs and on their offspring No deleterious effects whatever were observed the litters obtained from alcoholic parents, or from their descendants, were as numerous and as heavy as those from control matings and showed no excess of still births or deformities No transmitted defects were observed These results therefore fail to confirm those obtained by Stockard and published in 1913

Hormones

Dale and Gaddum have investigated the contractures of voluntary muscles, deprived of their ordinary motor nerve supply, which are elicited by stimulating the nerves which cause dilatation of their small arteries The muscles also react, by contractures, to the injection of chemical substances, of which acetylcholine is the most potent It appears almost certain that the nervous stimulation liberates acetylcholine and that the contracture is really due to the action of this substance upon the muscle fibres Eserine enhances the action of acetylcholine Matthes has found this effect to be due to the inhibition of the blood esterase, which hydrolyses it

Drury has continued his work on muscle adenylic acid and yeast adenosine both powerfully dilate the coronary arteries of the heart Adenosine may have a therapeutic value as a vasodilatant, since it is nontoxic

Marrian has continued his work on the chemistry of oestrin it can be readily extracted with ether from acidified urine obtained from pregnant women and purified by saponification and fractionation with solvents (see *Biochem Jour*, vol 23, p 1233, 1929 vol 24, pp 435, 1021, 1930) The crystalline substance has a very high activity

Gaddum has shown that a relatively simple polypeptide containing thyroxine, isolated from the thyroid gland by Harington by treatment with digestive enzymes, is as effective as *l* thyroxine when injected subcutaneously into the rat, but much more effective than the latter when both are given by the mouth

Pathological Researches

In conclusion, brief reference may be made to a few of the numerous researches of a pathological or bacteriological nature A report by the Departmental Committee of the Ministry of Health, on maternal mortality and puerperal fever, with which the Medical Research Council has been collaborating, has shown that 40 per cent of deaths are due to septic infection, 20 per cent to toxæmias, and 40 per cent to various accidental causes The prevention of the latter needs the better application of known means, our knowledge of the toxæmias is still imperfect, but administration of large doses of alkalis has been found to have a beneficial effect in the renal complications of pregnancy Research on the organisms responsible for puerperal fever and on methods of prevention and treatment is being actively pursued, and will be assisted by the building of a special block for septic cases at the new Queen Charlotte's Hospital at Hammersmith

Dunkin and Laidlaw have continued their work on canine distemper A method has been devised for measuring the progress of antibody production, the antiserum will fix complement in the presence of the virus, *in vitro*, and the reaction may be a means of estimating the potency of the virus or of the antiserum Durable immunity to the disease can be produced by injecting the serum and the virus at the same time into another part of the body, so that the whole process of immunisation can be performed on a single occasion

Dobell has completed some prolonged studies on the *Entamœba histolytica*, the cause of amœbic dysentery in man The organism can now be maintained indefinitely in artificial culture and any stage in its life history can be produced at will, it can be inoculated into a macaque monkey and the infection eradicated at will by therapeutic means Conditions affecting either host or parasite separately, or both, together can therefore be studied in detail these researches should pave the way for a really efficient treatment or prevention of the disease in human beings

The Paris Observatory.

It has been decided to close the Paris Observatory and erect a new national observatory at a cost of £400,000 in the Durance region of Provence, retaining the old building as a repository for equipment not in use and the many historic instruments the Observatory possesses It is many years since the proposal to remove the Observatory was initiated, and the present decision has been taken mainly on account of the difficulty of carrying on observations, due to the prevailing atmospheric conditions and to the vibration caused by the heavy volume of motor traffic in the neighbourhood

Though the decision is undoubtedly a right one,

many will regret the passing of an institution which has played a prominent part in the scientific life of the French capital Situated about half a mile south of the Luxembourg, the Observatory was built in the reign of Louis XIV to the designs of Claude Perrault, the famous architect of the Louvre It was begun in 1667 and completed in 1671—four years before the erection of Greenwich Observatory—and Dominique Cassini, the Italian astronomer, was appointed the first superintendent

In spite of the eminence of its designer, the building was not well adapted for its purpose, for as Grant says, "No means were provided in the construction of the building for enabling the astronomer to observe the celestial bodies at all altitudes, by means of instruments sheltered under its roof, nor was it possible to repair the omission, on account of the enormous thickness of the walls" Neither was its organisation one which was likely to lead to the best results Though Cassini was appointed its nominal head, no fixed sum was set apart to provide for the annual maintenance of the establishment No definite plan of observation was drawn up, and the Observatory was available for other astronomers desirous of prosecuting their own lines of study Cassini began his observations at the Observatory on Sept 14, 1671, Picard his on July 9, 1673, and La Hire his in 1677 Six years later a mural quadrant of 5 ft radius was installed and with this instrument La Hire made meridional observations for thirty years Four Cassinis in all were successively at the head of the Observatory, their combined periods of office extending over a hundred and twenty years

With the nineteenth century many changes were introduced, and the Paris Observatory has had a succession of directors whose names have become household words From 1830 until 1853, Arago was the director, but it was his successor, Leverrier, who became the real organiser of the Observatory Newcomb, who stayed in the Observatory as a guest of Delaunay during the Commune in 1870, said Leverrier's work 'was not dissimilar to that of Airy at Greenwich, but he had a much more difficult task before him, and was less fitted to grapple with it" Early in 1870, Leverrier indeed had become so unpopular that he was removed from office, but in 1872, on the tragic death of Delaunay, he was reappointed director He continued to hold office until he died in 1877, and for many years his statue has stood in the Cour d'Honneur

The reputation of the Paris Observatory has been raised still higher under the regime of Leverrier's successors, Mouchez, Tisserand, Loewy, and Baillaud, who, as Newcomb remarked in his "Reminiscences of an Astronomer", "have known where to draw the line between routine on the one side and initiative on the part of the assistants on the other" The pages of Nature have frequently contained notes on the progress of work carried out at the Observatory

Obituary

Prof Otto Wallach

In Otto Wallach, German chemistry loses one of its organic pillars He is almost the last to go of a great generation which believed in the serious study of materials at the laboratory bench as the prime and proper occupation of the chemist and could express itself in plain, straightforward, honest language, free from illusions and pretence The split *p* and the proton leaning post have changed all that the beginner no longer learns even to determine the molecular weight of oxygen, although he is prepared to discuss the 'in'ards' of its atoms, analysis is a meaningless word to him, he is not really to be trusted to analyse anything, either by word or deed What was a moral science is fast becoming mere superstition to the majority The example of a craftsman like Wallach is therefore of special value Devoting himself to the study of one of the great groups of plant products, the essential oils, he developed consummate analytical skill in unravelling Nature's most tangled mixtures, thus laying not only foundations for the future study of vital products but also contributing largely to the development of a most remunerative industry

Wallach was born on Mar 27, 1847, at Königsberg, Prussia, he died on Mar 1 Educated at a humanistic gymnasium in Potsdam, his university studies were carried on at Gottingen, where he came under Wohler, probably a greater chemist than his partner, Liebig, Fittig, a most accurate but unimaginative worker, and Hübner, a man of lesser note, he then spent a term in Hofmann's laboratory in Berlin After taking his degree in Gottingen in 1869, he passed the winter in Berlin as assistant to Wichelhaus, becoming assistant to Kekulé in Bonn in the spring of 1870 Part of 1871 was spent in the Berlin Aktiengesells für Anilinfabrikation In 1872, he returned to Bonn as laboratory assistant He became a *Privat-Docent* in 1875 and *extraordinarius* in the following year Thirteen years later, he succeeded Victor Meyer at Gottingen

Wallach's career therefore was neither adventurous nor rapid He began his work on essential oils in 1884 His industry so impressed the electors that, in 1910, as all good German chemists do, he received a Nobel Prize If an infinite capacity for taking pains be the mark of genius, he was definitely a genius, if imaginative power and a developed artistic and critical sense be the criteria, he was simply a highly competent workman a good cook, able to serve up dish after dish in well garnished form, scarcely a *chef* of high degree He was not even a pioneer but took up the ball, at a propitious moment, when the development of structural and synthetic chemistry was in

full swing and help was coming in from every quarter following it closely, happily aided by the inspired action of men like Tiemann and Baeyer, who every now and then gave to it a guiding kick, he was able to carry it forward with ever growing advantage, the score of papers to his record being ultimately 179

The first foundations of terpene chemistry were laid in France, especially by Berthelot Gladstone and Wright were early in the field here but did not get very far In the early 'seventies, Tilden and I began to revise and extend the French work but the real cause of advance was Tilden's brilliant discovery of the beautifully crystalline nitrosochlorides and nitroso derivatives of turpentine (pinene) and citrene We were early convinced that the number of isomeric hydrocarbons had been greatly exaggerated Wallach began by studying wormseed oil but soon passed into our field—without ever asking our permission, although those were days when not all were pirates as now He scored his first real success in working with Tilden's compounds It was therefore amusing when, in 1890, in a paper in the *Annalen* he practically accused me of having picked his brains when I had visited his laboratory shortly before This was in connexion with sobrerol As a matter of fact, I had been collecting the material a dozen years previously it was in this work that Sir William Pope's crystallographic genius first became apparent

If we ask why Tilden, who made so brilliant a beginning, did so little afterwards, whilst Wallach who had trod in his footsteps did so much the answer is that in 1880 Tilden became the head of a new school (Mason College) and had 'fish to fry' more important than essential oils Wallach had not a few helpers, under the German university system The last thing Birmingham cared for then was research Tilden had scarce a student to work with him his men were under no Ph D compulsion to attempt original work I was in a like position and, at about the time Wallach began, had three new laboratories on my hands in rapid succession Still we kept the camphor pot boiling usefully, so that an English camphor school gradually arose, this began by doubting Kekulé Perkin junior's synthetic terpene work stands unrivalled Later English workers in the field have given proof that there are still craftsmen among us Maybe, ere long we shall have to show that not a few of the conclusions of the Wallach school are unsound

Wallach was able to accomplish his work because he was under conditions which were the outcome of centuries of loving care for the universities and a public belief in the value of education Here, fifty to sixty years ago, even Oxford and Cambridge were scarce known to natural science Cambridge came fairly rapidly to the fore but Oxford was slower Meanwhile schools of university rank have been established in every considerable town in the country, perhaps some of us who have contributed to this end may prove to have done work of far more value than that on essential oils

Henry E Armstrong

We regret to announce the following deaths

Mr T C Cantrill formerly of the Geological Survey of Great Britain on April 3, aged sixty three years

Sir John de Villiers, noted especially for his work while in charge of the map room at the British Museum and his contributions to geographical and historical literature, on April 2, aged sixty seven years

News and Views

The Society for the Preservation of the Fauna of the Empire performed a great service when it persuaded the Secretary of State for the Colonies to approve of and support a general survey of the East African group of Colonies and Dependencies from the point of view of the preservation of wild life A fortunate choice selected as observer Major R W G Hingston, already well known for his natural history observations, and after a rapid survey of the land, the results and conclusions of his tour were presented on Mar 9, in the form of a lecture to the Royal Geographical Society Major Hingston had the advantage of discussing with Government officials and representatives of public opinion the problems which face the fauna of Africa, and on the basis of these discussions and his own observations he has submitted for the consideration of H M Government a scheme of nine national parks, which, if brought into being and effectively conducted, would ensure the perpetual preservation of the fauna of these territories, without undue interference with native rights or economic development To anyone familiar with the history of wild life in Africa, the gradual but constant retreat and often final extermination of the large animals is a commonplace, but surely Major Hingston exaggerates when he states that "great and small, everything is retreating" The general experience is that cultivation of the soil *increases* the amount of wild life, only, the great animals go, and the small things that take their place, even if they do not become pests, far from compensate for the picturesqueness of the departed

The large animals are at the mercy of several disruptive forces Of these, man has brought into play cultivation of the soil, the demands of special trades, and the activities of sportsmen, while Nature threatens with epidemic diseases Not only has African wild life suffered directly from such diseases, but the suspicion that it may harbour or encourage diseases to which man is subject has concentrated a new warfare against it, so that last year 20,000 head of game, including 9000 zebra and 2500 wildebeest, were slaughtered in Zululand because it was feared that they kept alive the tsetse fly with its burden of sleeping-sickness National parks and game reserves at present help to preserve the wild life of Africa, but the perma-

ience of the latter is uncertain, since their establishment or dissolution depends simply upon a proclamation in the local Government *Gazette*, agreed to by the Secretary of State. National parks, on the other hand, are more stable, made by Act of Parliament the property of the public for ever, to be utilised for the sole purpose of preserving the natural objects within them. "It is the belief", declared Major Hingston, "of all who desire the perpetuation of the fauna, that national parks on this rigid basis should replace the fluid reserves." Accordingly, he describes a series of nine national parks ranging from South Central Africa to the gorilla territory of Uganda. It is important that these parks should be created before wild life approaches the stage of disappearance. Not only will delay make them less effective for their prime purpose, but also it will add to the difficulties and cost of establishing them.

OF the many inventors from whose work has gradually been evolved the modern safety bicycle, James Starley, the centenary of whose birth occurs on April 21, was one of the most successful. By his improvements, it has been said, he rendered bicycles and tricycles machines capable of general use, while to his perseverance and energy Coventry owes its position as the centre of the cycle industry. The son of a Sussex farmer and born at Albourne, he began work on the land at the age of nine and at fifteen was a gardener in the employ of the famous marine engineer, John Penn, at Lewisham. A born inventor, he abandoned gardening for mechanics, and first in High Holborn and then in Coventry was employed in the manufacture of sewing machines. On the introduction of the French 'boneshaker' bicycles into Great Britain in 1868, their manufacture was taken up by the Coventry Machinists' Company, in which Starley was a foreman, and by him quickly improved. Patenting a method of tightening the wire spokes of tension wheels, in 1870 he brought out the "Ariel" bicycle, the first attempt to produce a light all-metal machine, and from this sprang the well-known 'ordinary' or 'penny farthing' bicycle. Starting in business for himself in 1872, he quickly gained a reputation for his machines and became known as the 'Father of the Bicycle'. He died on June 17, 1881, at the early age of fifty years, and was buried in the Cemetery, Coventry. Three years later, a monument was erected in Queen's Road bearing his portrait and representations of some of his machines. His nephew, J. K. Starley, also made notable improvements on bicycles, and in 1885, with Sutton, brought out the "Rover" bicycle, which embodied most of the features of the present safety machine.

AN exhibition of British glass and glassware was held in the exhibition hall of Messrs. Selfridge and Co., Ltd., Oxford Street, London, April 13–18. The exhibition was organised by the Glass Manufacturers' Federation in order to indicate to the general public the variety and quality of the products of the glass industry. The exhibits included artistic glassware and fine crystal tableware; glass bottles and jars of various shapes and sizes; sheet glass in different forms and plate glass from ⅛ inch in thickness to 1½ inch; glass transparent to ultra-violet light, and glass which excludes about 80 per cent of the heat rays. The varied range of exhibits of chemical, scientific laboratory, and medical glassware, and of fused silica glassware, gave evidence of the remarkable progress that has been made in these branches of the industry. The application of glass in the electrical industry was illustrated by wireless valve bulbs; electric lamp bulbs, which are produced by automatic machinery; a 10 kw. electric lamp, such as is used in lighthouses and in aerodrome pilot lights; photo-cells; and neon lights for decorative and publicity purposes. Two large blocks of fine optical glass were shown, and also a polished telescope disc of 24 inches diameter. Amongst the spectacle lenses exhibited were samples of specially computed cataract lenses of light weight, and trifocal lenses made by fusing as many as six pieces of glass to form the complete lens. Spun glass, known as glass silk or glass wool, was shown in skeins and also woven into cloth and mats. This is now being largely manufactured and used for heat insulation purposes on boilers and steam pipes. It is more efficient than many other substances used for this purpose, and, in the form of mattresses or strips, can be easily and quickly applied or removed.

AT the quarterly meeting of the Grand Council of the British Empire Cancer Campaign held on April 13, the finance report showed that, including the grants approved at the meeting, the Campaign had now subsidised research centres and independent research workers, since its inception, to the extent of £157,000. Apart from this, a sum of more than £500,000 had been subscribed and is being administered by the branches and affiliated organisations of the Campaign throughout the British Empire. On the recommendations of the Executive Committee, the Grand Council approved the following grants: £2500 to the Cancer Hospital (Free) for its general research work, together with an additional sum of £500 to meet the expense incurred by the Research Institute by the appointment of its bio-chemist, Dr. J. W. Cook; £650 for one year to St. Mark's Hospital, City Road, and £2500 to St. Bartholomew's Hospital. For the sixth year in succession, the Grand Council renewed the grant of £680 to the Medical Research Council towards the upkeep of the Radon Centre at the Middlesex Hospital, which supplies a number of organisations with radon for scientific experimental investigations. Prof. W. S. Lazarus-Barlow was elected to fill the vacancy in the five nominees of the Campaign on the Scientific Advisory Committee, the other five members of which are nominated jointly by the Royal Society and the Medical Research Council. The Grand Council acceded to the request that the Glasgow Royal Cancer Hospital should be affiliated officially to the British Empire Cancer Campaign.

THE "Unusual Ice Formation" described by Prof. A. Morley Davies in NATURE for Mar. 7, p. 340, has also been recorded by Mr. W. B. Alexander at Reigate on the morning of Jan. 2, 1931. The latter formation consisted of a pencil-shaped column of ice 3¾ in. high

and ⅜ in in diameter, rising vertically from a glass bowl about 4 in in diameter and containing nearly 2 in of water A similar phenomenon, illustrated by a very fine photograph, was described by Mr Basil Longley, of Crawley, Sussex, in the *Meteorological Magazine* for March 1929, and there are probably other descriptions extant In all these cases the method of formation was probably along the lines described by Prof Davies Mr Longley explains it as follows "the water froze rapidly on top, and when the expansion took place underneath, the surface ice broke (this can be seen) and owing to the continuing pressure of the water expanding, it gradually oozed out, freezing as it came There was a tiny hole up the centre of the column which justifies this theory " The volume of Mr Longley's column was, roughly, one hundredth of the ice in the bowl, of Mr Alexander's about one sixtieth, and of Prof Davies' (if it was solid) about one fifteenth , the expansion of water in freezing is about one tenth, but the formation of the columns could not begin until a fair thickness of ice existed on the surface The order of magnitude is approximately correct, but the formation evidently requires a high degree of cohesion between the ice and the sides of the bowl, as well as certain definite conditions of temperature, thus accounting for its rarity

A NEW record for a long distance flight in a light aeroplane has been set up by Mr C W A Scott, who left Lympne aerodrome on April 1 and arrived at Darwin, in the Northern Territory, Australia, on April 10 His time for the journey was 9 days 3 hours 40 minutes, thus beating Air Commodore Kingsford Smith's time for the same flight last autumn by about nineteen hours Mr Scott's machine is a Gipsy Moth light aeroplane, specially fitted with fuel tanks carrying about a third of a ton of petrol, and the engine is a de Havilland 120 h p Gipsy II , the same pattern as that used by Kingsford Smith Its cruising speed is about ninety miles an hour According to a long communication from Mr Scott in the *Times* of April 11, his course was from Lympne across Europe to Belgrade, on to Aleppo, then to Baghdad, Gwadar in Baluchistan, Karachi, Calcutta, Rangoon, Singapore, Bima, and then across the Timor Sea to Bathurst Island and Darwin His longest day was 15 hours 45 minutes, covering 1450 miles, and total flying time and distance, 109 hours 50 minutes and 10,450 miles That the aeroplane successfully withstood the strain of this flight must be very gratifying to the designers and makers of both engine and machine, while the flight itself is a noteworthy feat of personal endurance and skill

IN a paper read before the New York Electrical Society on Mar 19, Dr Goldsmith discussed what he calls the "new music of electric vibrations" He illustrated it by a novel device called the electric carillon, which can send out bell tones louder than any bell in the world A series of small steel chimes not unlike those of a household clock are struck by little electric hammers actuated by a keyboard similar to that of a piano The sounds thus produced are only audible a few inches away but the vibrations of the steel chimes create small electric currents in devices like the 'pick up' used in electric gramophones These feeble currents are amplified millions of times by vacuum tube amplifiers and can be clearly heard in the largest concert hall or for miles round a church tower by means of giant amplifiers The operator of the electric carillon not only controls the notes to be played but also can vary the volume of the tone to any desired extent Dr Goldsmith believes strongly in the future of electric music In his opinion, the musical artist of the future will become more and more indispensable The physical limitations which now weigh heavily on great artists will be largely reduced The number of notes which the musician can play per second will not be limited by the speed of his fingers T[illegible] of any origin can be made to resemble those of [illegible] desired instrument by electrical methods Each musician will be able to play not only the melody but also will be able to make it sound as if produced by any type of instrument The new electric music will gradually evolve a new type of composer capable of utilising to the full the capabilities of emotional expression contained in electric music Dr Goldsmith also demonstrated the 'theremin ', an electric musical instrument which is operated by moving the hands backwards and forwards in front of it It is called the theremin, after its inventor, a Russian physicist

In the *Engineer* of Mar 27, Mr H J Shepstone gives an account of the progress made with the scheme for supplying Palestine with electricity, generated in the valley of the River Jordan In its passage from its source in Mount Hermon to the Dead Sea, the river has a fall of no less than 3000 ft , and it discharges more than 5,000,000 tons of fresh water into the Dead Sea daily The entire scheme includes the provision of three hydro electric plants, the first of which has just been completed This station is situated at Jisr el Mujameh, some seven miles south of the Sea of Galilee For the storage and control of the water two dams and two concrete lined canals have been constructed and the first two units of 8000 h p each have been installed in the power-house When the demand warrants it, two other units will be installed, while later on a second power-house will be built at Abadieh and a t[illegible]rd at Jisr Banah Yakoub, which lie respectively south and north of the Sea of Galilee Transmission lines will connect the hydro electric plants with three fuel power stations at Jaffa, Haifa, and Tiberias, and in the near future, it is hoped, every city, town, and agricultural settlement will be able to obtain electrical energy

SMUT diseases, bunt of wheat in particular, are responsible for considerable loss of grain in England, and the illustrated bulletin (No 24) recently issued by the Ministry of Agriculture entitled "Cereal Smuts and their Control" should prove of great benefit to the farmer The symptoms and mode of infection of these diseases in wheat, barley, and oats are described, and methods of control, fairly simple to carry out and of moderate cost, are given in detail,

Attention is directed to the necessity for distinguishing between 'covered' and 'loose' smuts, for whereas in the former, contamination with the fungus is on the outside of the grain only, in the latter the infection is internal, and the appropriate methods of control are accordingly different in the two cases. For prevention of 'covered' smuts, of which bunt in wheat is an example, treatment or 'pickling' with formalin (1 pint of 40 per cent formaldehyde to 40 gallons of water) is recommended as preferable to the older method of steeping or spraying with copper sulphate. The advantages afforded by a dry type of treatment are obvious, and mention is made of recent successful trials of powder pickling with copper carbonate. The control of 'loose' smuts offers a much more difficult problem, as external application of a fungicide is useless. Steeping the grain in hot water appears to be the only known remedy, but the temperature necessary to kill fungus is very close to that fatal to the grain, so that the method is attended with considerable difficulty. Copies of the bulletin may be obtained from the Ministry of Agriculture, 10 Whitehall Place, London, S.W.1. Price 5*d*. post free.

PRELIMINARY reports on the work of the expedition of the Royal Anthropological Institute to Kharga Oasis, organised and led by Miss Caton Thompson with Miss E. Gardiner as geologist, justify the choice of this little explored area as the scene of the past season's work, and hold out strong hopes for the future. Thanks to the co-operation of Lady Bailey, and with the permission of the Egyptian and British Governments, an aeroplane and air photography were at the disposal of the expedition for a period of two weeks. By this means and with the additional assistance of camel transport, it was possible to examine the area thoroughly, and points of archæological importance were marked down for future seasons' investigations. In addition to the work of reconnaissance, the history of the springs of the floor of the oasis was investigated. This brought to light a deeply buried Mousterian culture of special ised type, showing affinities with cultures in Algeria and Tunisia. Another notable find was extensive flint workings, extending for some miles along the edge of the Kharga Scarp, the second only of its kind to be found in Egypt. A short account, with illustrations, of the results appeared in the *Times* of April 13.

THE *Polar Record*, of which the first number has just appeared, is a modest journal which it is proposed to publish twice a year from the Scott Polar Research Institute at Cambridge (price 1*s*.). It is to be the official organ of that institute, and though at present merely a record of news of exploration in polar regions, it is hoped gradually to extend its scope. The first number starts well and should be full of interest to that small but growing group of explorers and students of polar regions. News is given of Norwegian work in Svalbard, Russian in Franz Josef Land and Northern Land, and German, British, American, and Danish in Greenland. There are also some details of American, Norwegian, and British work in the Antarctic, where important discoveries have been made during the last few months. The number concludes with a short bibliography of recent polar books.

THE issue of the two index numbers of *Science Abstracts* completes the physics and the electrical engineering sections of volume 33 (1930). More than 200 periodicals are abstracted by 76 abstractors, most of whom are specialists in the particular branch of the subject with which they deal. The physics volume has 4165 abstracts of average length 0.267 page, and 230 pages of index; the electrical engineering volume, 2537 abstracts of average length 0.282 page, and 134 pages of index. The volumes are essential in every library consulted by physicists or electrical engineers who desire to keep themselves up to date.

AT the annual meeting of the Gilbert White Fellowship held on April 11, Sir John Russell was elected president and Prof. E. J. Salisbury and Prof. W. H. Wagstaff were elected vice-presidents.

A MEMORIAL to Admiral of the Fleet Sir Henry Jackson, which has been placed in the crypt of St. Paul's Cathedral, was unveiled and dedicated on April 13. It is in the form of a tablet, recording the principal posts he hold and referring to the services he rendered to the Navy. Sir Henry's scientific work was described in an article in NATURE of Jan. 11, 1930. His chief work was a pioneer investigation into problems connected with the transmission of signals by wireless telegraphy, a piece of research inspired by some experiments by Sir Jagadis Chunder Bose on coherers. Under Sir Henry's personal supervision, this type of communication was installed throughout the Navy.

AT the annual election of office-bearers of the Royal Philosophical Society of Glasgow, on Mar. 25, the following officers were elected: *President*, Prof. W. R. Scott; *Vice-President*, Dr. J. W. French; *Hon. Treasurer*, Sir John Mann; *Hon. Librarian*, Dr. J. Knight; *Hon. Auditors*, Mr. John J. D. Hourston and Mr. James A. French; *Acting Secretary*, Dr. James M. Macaulay. During the session, Sir Donald MacAlister, chancellor of the University of Glasgow, Sir C. V. Raman, professor of physics in the University of Calcutta, and Prof. F. O. Bower, emeritus professor of botany in the University of Glasgow, were elected honorary members of the Society.

ACCORDING to a notice issued (in Latin) from the Vatican City on Mar. 15, the Pontifical Academy of Sciences (Nuovi Lincei) is inaugurating the broadcasting of notes and information on mathematics and the experimental sciences and their applications. In general, the language used will be Latin, but for notes referring to investigations or discoveries the author's own language may be employed, and for matters of great importance other languages may be utilised. A general invitation to supply material for this purpose is expressed, and all communications submitted will be considered by a committee of the Academy. Notes giving the results of scientific work should consist of about 300 words, and items of

information of about 100 words Communications should be addressed "Pontificia Academia Scientiarum Comitatui pro Nuncio Radiophonico, Città del Vaticano"

At a meeting of the Council of the Royal College of Surgeons on April 10, the Jacksonian Prize for 1930 was awarded to Mr Edgar S J King, of the University of Melbourne, for his essay on "The Pathology of Ovarian Cysts and its Bearing on their Treatment" A certificate of honourable mention for an essay on the same subject was granted to Wilfred Shaw, of St Bartholomew's Hospital The John Hunter Medal and Triennial Prize for 1928–30 was awarded to Mr Layton, of Guy's Hospital, for his contributions to otology and for his valuable services to the museum, particularly in connexion with the Onodi Collection The Walker Prize for work on the pathology and therapeutics of cancer for 1926–30 was awarded to Sir G Lenthal Cheatle The Cartwright Prize for 1926–30 was awarded to Mr F W Broderick for his essay on 'The Etiology Pathology, and Treatment of Chronic General Periodontitis (*Pyorrhea alveolaris*)'

The twenty first annual May Lecture of the Institute of Metals will be given on Wednesday, May 6, by Mr William B Woodhouse, engineer and manager of the Yorkshire Electric Power Company, on "The Progress of Power Production" Tickets for the lecture may be obtained from the Secretary of the Institute of Metals, Members' Mansions, Victoria Street, London, S W 1 The autumn meeting of the Institute of Metals is to be held in Zurich on Sept 13–18 by kind invitation of the Schweizerische Verband fur Materialprufung The evening of Sept 13 will be devoted to the formal opening of the meeting, addresses of welcome by the inviting body, and the Autumn Lecture, to be given by Mr U R Evans, on "Thin Films on Metals in Relation to Corrosion Problems" The mornings of Sept 14 and 15 will be devoted to the reading and discussion of papers, whilst for the afternoons visits have been provisionally arranged to works in Zurich and its neighbourhood On Sept 18 the main party will divide, one part going to Biel to visit a watch factory and leaving for England in the evening, whilst the other will go via Lotschberg to visit the new aluminium alloys rolling mills at Chippis Siders, in the Rhône Valley From Chippis the party will either return to London via Lausanne or Geneva, or proceed via the Simplon to Milan to take part in the International Foundry Exhibition and Congress, which continues at Milan until Sept 27 The first congress of the New International Association for Testing Materials is being held at Zurich during the week preceding the Institute of Metals meeting

We have received from Messrs A Gallenkamp and Co, Ltd, Sun Street, London, E C 2, their catalogues of electrochemical apparatus and colorimeters (Lists No 80c and No 92) In the former will be found listed apparatus for electro analysis, the electrometric determination of hydrogen ion concentrations, and the measurement of conductivity of electrolytes Ammeters, voltmeters, galvanometers, and thermostats are included In the section on hydrogen ion concentration, a useful summary is provided of the use of the hydrogen electrode, with descriptions of other types, including the quinhydrone and glass electrode In the second list, numerous types of both simple and more complicated colorimeters are detailed, including two modern patterns of the Lovibond tintometer The catalogue gives a good idea of the range of instruments of this type which are at present on the market, and should be of use to biochemists and physiologists

A short but useful list of scientific journals and transactions of learned societies has just been issued by Messrs Oppenheim and Co (Rare Books), Ltd, 317A Fulham Road S W 10 In several cases complete sets are offered for sale

Librarians and others interested in the Far East should obtain a copy of Catalogue No 534, "Orientalia", just issued by Francis Edwards, Ltd, 83 High Street, Marylebone, W 1 Particulars of upwards of 1000 works are given in it relating to Burma, Ceylon, China, the East Indian Archipelago, Formosa India, Japan, Korea, Persia, Siam, Tibet, and general works

A good catalogue (No 364) of second hand books upwards of 2000 in number, has just been published by Messrs W Heffer and Sons Ltd, Petty Cury Cambridge It ranges over the subjects of agriculture botany, anthropology and ethnology, chemistry and chemical technology, mathematics, physics and engineering, physiology, anatomy and medicine, zoology and biology, and is strong in journals and other publications of learned societies

Applications are invited for the following appointments, on or before the dates mentioned —A senior secretary in the Matriculation and School Examinations Department of the University of London—The Principal ("M S E"), University of London South Kensington, S W 7 (April 25) A master under the Education Department of Southern Rhodesia to teach physics and chemistry at the Boys High School, Umtali—The High Commissioner for Southern Rhodesia, Crown House, Aldwych, W C 2 (April 30) A chief inspector of smoke nuisance under the Government of Bengal—The High Commissioner for India, General Department, India House Aldwych, W C 2 (April 30) Two fellows in psychiatry at the London Child Guidance Clinic, 1 Canonbury Place, N 1—The Secretary, Child Guidance Council 7 Buckingham Palace Gardens, S W 1 (May 2) An assistant lecturer in chemistry at the Liverpool Central Municipal Technical School—The Director of Education, 14 Sir Thomas Street, Liverpool (May 2) An assistant lecturer in physics at the University College of North Wales, Bangor—The Registrar, University College of North Wales, Bangor (May 16) A director of the Rubber Research Institute of Ceylon—The Chairman of the Board of Management, Rubber Research Scheme, Peradeniya, Ceylon (May 30) A lecturer in tinctorial chemistry and dyestuffs at the Manchester Municipal College of Technology—The Registrar, College of Technology, Manchester (June 5)

Research Items.

Daggers with Inlaid Handles.—In *Ancient Egypt*, 1930, No. 4, Sir Flinders Petrie, referring to the recent discovery in Palestine of two examples of the dagger having a metal handle cast in one piece with the blade and bearing a plate of inlay on each side, reviews a number of examples of the type which have come into view, in various countries. These he places in six classes: (1) The butt handle, of the simplest type, with a slight curve at the end and the inlay space shallow and long. It begins about 2000 B.C. near Behistun and is found at Nineveh and Ras Shamra. (2) The pommel type, begins with the butt getting wider as in Egypt; the distinct pommel appears in the south west of the Caspian; the fully developed pommel is on a dagger of Apepa III (1600 B.C.); the subjects are embossed on electrum plates. This type belongs to North Syria and was brought to Egypt by the Hyksos. (3) The encased handle begins with the deep setting of the handles as from Kasbek, Caucasus, about 600 B.C. The examples point to a primitive type of pierced bone handle. The encased inlay passed into a form like that of the deeply winged palstave. (4) To give the best grip to the handle for an upward thrust, a cusp was raised, giving the thumb and finger a more secure hold. A preliminary form appears in Hyksos times. It was a development of the tang made in shovel form to insert in a separate handle. (5) The wide blades with cross head handles are western. The inlay is riveted on. An example of about 1400 B.C. is from Korinth, others from Knossos, Veii, Cuma, and Terni. (6) The falchion (*khepesh*, the thigh), of eastern origin, an example from Diarbekr, of 1300 B.C., has an inlay handle with the name of Hadadnirari, and another of the time of Rameses II from Tell Retabeh.

Samoan Culture.—A detailed and exhaustive analysis of the material culture of Samoa by Te Rangi Hiroa (P. H. Buck) appears as *Bull.* 75 of the Bernice P. Bishop Museum of Honolulu. The summary of conclusions drawn is that canoes with top sides or planks joined by right through lashing associated with the rectangular house with wall posts and wall plate erected before the principal rafters were put up, the bow and arrow, slings, and such games as dart slinging, bowling with discs, and string figures constitute an early culture which spread over the whole Polynesian area. Certain culture traits such as the marae, stone figures, upright drums, and the nose flute passed into eastern Polynesia without affecting Samoa. The striking features distinguishing Samoan culture from the general culture of eastern Polynesia are the arched houses and the flanged plank canoes. Special efforts resulting in improved technique are closely related with class distinctions. Building and tattooing obtained their highest remuneration from the higher classes and these crafts were used to accentuate class distinction. The builders' guilds had more set rules than they had in eastern Polynesia. The Samoan system demands instant payment and immediate provision of food, as against the usual Polynesian system of reciprocal labour. Samoan material culture is uninspired.

Experimental Studies of Dengue.—Dengue is an acute, but benign, fever of 2-7 days duration and prevalent in the east. In the Philippines, the disease has recently been the subject of investigation by Majors J. S. Simmons and J. H. St. John, of the Medical Corps, and Captain F. H. K. Reynolds, Veterinary Corps, U.S. Army (*Philippine Jour. Sci.*, vol. , 1931, p. 1). The disease is caused by a filterable virus, and is transmitted by mosquitoes of at least two species in the Philippines, *Aedes egypti* and *A. albopictus*. It is shown that 5-10 infected mosquitoes convey the disease just as well as 150. The mosquitoes to become infected must bite the patient during the first two days of illness, but they do not transmit until twelve or more days later. It is probable that one attack of the disease confers a lasting immunity. Attempts to prepare prophylactic vaccines were unsuccessful. Attempts to transmit the disease to a number of animals failed, but evidence was obtained that two Philippine monkeys may act as reservoirs of the virus, and may be factors in the spread of dengue. A prolonged study of the blood during the course of the disease was made. An outstanding feature is a remarkable diminution in the white corpuscles at the height of the fever to one half the normal or even less.

A Bird Census in California.—Slowly increasing numbers of bird counts emphasise the variable size of the populations of areas of different character: there may be an average of less than a pair of birds to the acre in some places, and in others so many as fifty four pairs—both these record areas happen to be in the United States of America. A new region in California—the Lassen Peak Region—has been intensively studied by Joseph Grinnell, Joseph Dixon, and Jean M. Linsdale, and among the many interesting observations in their 500 page monograph appears a census of the birds (*Univ. California Publ. Zool.* vol. 35, 1930). The count covered an area of 6½ acres, searched daily at all hours of the day for 16 days in June, during the breeding season. Twenty four breeding pairs were established there, not quite four to the acre. Neither casual nor regular visitors to the checked area from other areas were included. The authors consider that the average population of the whole Lassen Region is over represented in the selected area, and from 'time' censuses and memory impressions they would place the general average at not more than one breeding pair to the acre. The results of the systematic study of the birds themselves suggest that where individuals of a particular species are sparsely distributed and the habitat greatly interrupted, the chances for developing and perpetuating local population strains are better than in an area of contrary nature. The mammals and reptiles of the Lassen Region, as well as the birds, give many apparently good cases illustrating this point.

True's Beaked Whale in the Hebrides.—An example of this very rare whale was stranded on the Outer Hebrides in January, and has been described by A. C. Stephen (*Scottish Naturalist*, 1931, p. 37). The length of the whale was 17 ft. 6 in., and the head, which is now in the Royal Scottish Museum, possesses the single pair of teeth, set at the extreme end of the lower jaw, which is a leading character of the species. Only twice before has this whale been found in British waters, on both occasions on the west of Ireland, and two further records, from the east coast of the United States of America, complete the known appearances of one of the most elusive of whales.

Spiders of Porto Rico.—The three parts of the work of this title recently issued (*Trans. Connect. Acad. Arts Sci.*, 30, 1-158, 159-335, 1929; 31, 1-191, 1930) represent the result of Prof. A. Petrunkevitch's stay as visiting professor to the University of Porto Rico during 1925-26. The spiders of the island are increased from 74 to 174 species in 100 genera; one genus and 72 species are new, and all are very fully described, with the help of 562 detailed diagrams. A

new method of describing the appearance of a spider's leg is introduced as being more accurate than words like 'stout' or 'slender'. This consists in expressing the breadth of the patella as a percentage of the united length of tibia and patella, and is known as the 'tibial index' Thus, for a pholcid the index is 2, for a theraphosid it is 13 A promised discussion of the Porto Rican fauna as compared with that of the other islands and of the clues as to its origin and evolution is eagerly anticipated

Echinoderm Oogenesis--L A Harvey (*Proc Roy Soc*, vol 107, 1930) discusses the cytology of oogenesis in *Antedon* and *Asterias* The chief difference noted is that in the oocyte of the former genus, a yolk nucleus is present, but not in the oocyte of *Asterias* Yolk appears in both under the influence of the Golgi apparatus, which consists of scale like dictyosomes visible in the living egg in *Antedon* but not in *Asterias* The mitochondria are early scattered in the cytoplasm and are present in large numbers It is suggested that they are concerned in the synthesis of yolk from raw materials in the cytoplasm Fat arises as minute droplets scattered among the yolk spherules, neither Golgi apparatus nor mitochondria are concerned in their appearance in the cell

Observations on Tetrarhynchids—Prof Th Pintner (*Sitz Akad Wiss Wien, Mat naturwiss Klasse* 139 Bd, 7 Hft, 1930) gives an account of the anatomy and systematics of some little known tetrarhynchid cestodes, with keys to the genera and species, and adds observations on the movements of the young encysted forms In the fresh liver of the teleostean fishes *Lepidopus* and *Brama*, the young worm lies motionless in the cyst, but as soon as the liver begins to decompose, movements in the head region begin Apparently only chemical or temperature stimuli will provoke these movements, for rough handling with a preparation needle produces no contraction The author suggests that a stimulus would be provided in the alimentary tract of the final host (an elasmo branch) when the liver is in process of digestion and would cause the larva to strive to free itself from the cyst The paper is illustrated by 73 figures

Researches on Diatoms—Miss S M Marshall and A P Orr continue their valuable researches on diatoms in their latest paper "A Study of the Spring Diatom Increase in Loch Striven" (*Journal of the Marine Biological Association of the United Kingdom*, 16, 3, 1930) Experiments with diatom cultures and sea water samples were carried on at the same time as the general studies During the three years 1926, 1927, and 1928, this increase was almost wholly due to *Skeletonema costatum*, which is able to grow within wide temperature limits There were very few other diatoms, and animals were scarce The pH value and oxygen content rose and the phosphate fell with the increase in numbers of diatoms It was found that temperature is not the direct cause of the beginning of the increase, but the density of the water which is influenced by the temperature is important, because it determines the amount of vertical mixing The vertical currents, besides bringing up the nutrient salts, carry the diatoms from the surface layers, where there is much light, to the deeper waters, where in winter and early spring there is not enough light for photosynthesis to balance respiration With the lengthening of the days and better weather conditions the depth at which photosynthesis may take place increases Regarding light intensity, it is shown that in Loch Striven the date of the spring diatom increase is apparently decided chiefly by the total light, which depends both on length of day and intensity

Crossing-over in Tetraploid *Primula sinensis*—An interesting paper by Miss D de Winton and Prof J B S Haldane (*Jour Genet*, vol 24, No 1) makes a comparison of the linkage relations in the diploid and the autotetraploid *Primula sinensis* Three factors are considered—*S*, which converts pin to thrum, *B*, which converts red flower to magenta, and *G*, which produces green stigma and ovary, inhibiting red Only *S* is fully dominant when present in one dose in the tetraploid Six of the seven possible types of linkage between these three factors in the tetraploid have been studied The intensity of linkage is about the same as in the diploid, but, unlike the diploid, there is no significant difference in the linkage on the male and female side The results agree well with theory, notwithstanding that Darlington (in the same number) has found numerous meiotic irregularities in the $4n$ form No evidence was obtained of crossing-over between more than two chromosomes of a set at one time, nor of two chromosomes going to the same pole after crossing over The results to be expected in the offspring of the different types of tetraploid zygote when selfed, with or without crossing over, are given in a useful table

'Collapse' in Australian Timber—C Sibley Elliot, assistant seasoning officer of the Australian Division of Forest Products, has an interesting paper in the *Journal* of the Council for Scientific and Industrial Research, vol 3, No 4, upon the occurrence of 'collapse' during drying of Australian timbers This is entirely different from the normal shrinkage and swelling of timber with changing water content Shrinkage is associated with an approach of the fibres towards one another as the timber dries, and cannot be prevented 'Collapse', on the contrary, involves the actual breaking down of many of the microscopic tubular elements in the wood, and it is frequently accompanied by considerable distortion in consequence 'Collapse' occurs in several of the Australian eucalypts to a considerable extent, in Australian grown timber it occurs mainly in the young outer wood or in wood from the upper part of the tree It may occur when the water content of the wood is still relatively high (more than 80 per cent), and has been attributed by H D Tiemann, of the Forest Products Laboratory, Madison, U S A, to the stresses set up within the wood by the continuous films of water in drying wood when air is unable to enter Whilst shrinkage of wood is inevitable as moisture content changes, the collapse can be corrected and permanently removed by the prolonged action of steam after the timber has been previously dried to a moisture content of 10 12 per cent This process, under the name of 'reconditioning timber', has been successfully adopted under commercial conditions in many large scale plants in Australia

Palæozoic Diatoms—An illustrated account of diatoms found in deposits of Carboniferous and Permian age is given by D Vito Zanon (*Mem Accad. Scienze, I Nuovi Lincei*, ser 2, vol 14, 1930, p 89) Some sixty species are recognised, most of which are identified with living forms

The Atlas Mountains—In the *Scientific Monthly* for February, Prof H C Lawson discusses the origin of the Atlas mountains of Morocco They have the characteristics of a youthful range, with narrow valleys, sharp ridges, and peaks The torrential streams flow in trenches far above the base level of erosion Features such as these cannot have survived from the time of the Alpine uplift, and Prof Lawson argues that the Atlas have undergone a rejuvenation His

reading of the evidence, which he details in full, is that at the end of the Eocene the Alpine uplift gave rise to what he calls the Alpine Atlas, on the site of the geosyncline which occupied part of the area of the submerged peneplain that succeeded the Hercynian mountains. By the end of the Tertiary period the Alpine Atlas had been reduced to a past mature hill range and the surrounding country to a peneplain. Then came the rejuvenation which led to the present Atlas. This was due to two movements: a broad arching which uplifted the peneplain to about 1200 metres, and a sharp orogenic upthrust between marginal faults. The degradation of the upthrust mass and consequent loss of load induced further rise by isostatic adjustment. The depressions flanking the range are explained as due to sinking of material in compensation for loss of load on the range.

The Atlantic Earthquake of 1929.—Two interesting papers on the earthquake of Nov. 18, 1929, by D. S. McIntosh and Dr. J. H. L. Johnstone appear in the *Transactions* of the Nova Scotian Institute of Science (vol. 17, pp. 213-222, 223-237, 1930). See also the letter by Prof. J. W. Gregory in NATURE, vol. 124, pp. 945-946, 1929). The cable breaks all occurred from lat. 39° 29′ to 45° 6′ N. and long. 52° 10′ to 57° 56′ W., that is, within an area of about 60,000 sq. miles, in a line with the old submerged portion of the St. Lawrence river. The depths at which the cables were broken range from 44 to 2934 fathoms, and the officers in charge of the repair work found no difference from the charted depths greater than those that might be due to errors in sounding. In many cases, the broken cable ends were found buried in mud or gravel. The ends appear as though the cable had been cut by a dull pair of heavy scissors, except at one spot (in lat. 43° 27′ N., long. 56° 13′ W.) where "the cable was found broken up in short lengths and the core twisted round the sheath. The wires of the sheath were bent back on themselves two or three times, wound around the core, and the latter twisted about the heavy galvanised steel sheath." From seismographic evidence, the epicentre is estimated by Messrs. Hodgson and Doxsee to lie in lat. 44° 5′ N., long. 55° 15′ W., which is nearly that obtained from the times of arrival of the sea waves at Halifax and the Newfoundland coast.

Variations of the Solar Constant and Terrestrial Weather.—Dr. C. G. Abbot, in a paper entitled "Weather dominated by Solar Changes" (*Smithsonian Miscellaneous Collections*, vol. 85, No. 1) continues his studies of variations of the solar constant and their influence on terrestrial weather. He finds that periods of increasing or decreasing solar radiation are followed by changes of pressure and temperature at Washington. These changes are irregular and differ considerably in different months, but those following increasing radiation are, on the whole, opposite to those following decreasing radiation, suggesting that though difficult to understand, they are probably real. An additional test is obtained by investigating the solar constant for periodicities; by a graphical method lengths of 8, 11, 25, 45, and 68 months are found, the combination of which reproduces the original curve with reasonable accuracy. The monthly mean temperatures at Washington for the period 1918–30, corrected for annual variation, are then analysed for the same periodicities and the results, with the addition of a terrestrial period of 18 months, are combined to form a curve not unlike the original. It should be remarked, however, that Dr. Abbot does not point out that the phases of the periodicities of temperature at Washington have no definite relation to the phases of the corresponding solar cycles. Moreover, if the 18-month periodicity is omitted, the calculated temperatures have a correlation of only 0.36 with the observed figures, so that they cannot be said to be "dominated" by solar changes, and the relationship will have little value for forecasting.

Lubrication and Viscous Flow.—Several investigators of lubricating oils have found that, when such oils are allowed to flow for some time through capillary tubes of internal diameter of 0.3 mm., the tubes become clogged in a few hours. This clogging has generally been explained as due to the orientation and adsorption of the polar constituents of the oil by the walls of the tube, and in the first Report of the Lubrication Research Committee, Sir William Hardy expressed the opinion that none of the liquid between two solid surfaces is free unless it is at least 5×10^{-4} cm. from each surface. The January issue of the *Journal of Research* of the U.S. Bureau of Standards contains a paper by Dr. R. Bulkley giving an account of his measurements of the flow of oils through capillary tubes, which have been carried out with the support of the Research Committee on Lubrication of the *American Society of Mechanical Engineers* to test whether this adsorption by the walls takes place. He finds that when the oils are filtered through porcelain before entering the capillary tube, they show no signs of clogging even in tubes of 11×10^{-4} cm. diameter. He considers that the evidence points more in the direction of slipping of the oil at the wall, or, if there is any increase of the viscosity of the oil near the wall, that increase does not extend more than 0.02 or 0.03×10^{-4} cm. from the wall.

Free Radicals.—Conant, Small, and Taylor in 1925 showed that halochromic (coloured) salts of triphenylcarbinol and related substances are reduced by powerful reducing agents in appropriate solutions with the formation of the free radical (for example, triphenylmethyl). A similar result would be expected in regard to the cations of the triphenylmethane dyes, except that the resulting free radical would probably be even less stable in acid solution than triphenylmethyl. In the February *Journal of the American Chemical Society*, Conant and Bigelow show that these expectations are confirmed by experiment. The following general reactions are assumed, in which R^+ is the dye cation and M^{++} the titanous, vanadous, or chromous ion used in reduction:

(1) $R^+ + M^{++} \rightleftharpoons R$ (free radical) $+ M^{+++}$,
(2) $2R \rightleftharpoons R-R$ ('ethane'),
(3) $2R + H^+ \longrightarrow RH$ ('methane') $+ R^+$,
(4) $2R \longrightarrow R_2$ (Chichibabin compound).

Reactions (1) and (2) are reversible and rapid; (3) and (4) are irreversible. The products of reactions (2), (3), and (4) were isolated in the case of malachite green and *p*-dimethylamino triphenylcarbinol. In order to isolate the associated free radical ('ethane'), advantage was taken of its relative insolubility in aqueous solutions of *p*H 3. The solutions absorb oxygen very rapidly, as much as 89 per cent of the amount required for peroxide formation being taken up by the crude dried material. The nomenclature used in (4) is based on the analogous formation of *p*-benzhydryl tetraphenylmethane from triphenylmethyl, first observed by Chichibabin, although the structures of the dimers obtained, isomeric with the 'ethanes', have not been established. Their empirical formulæ show them to be dimolecular reduction products of the cations. The action of vanadous or chromous chloride on the keto chloride of Michler's ketone is similar to the reduction of salts of the diphenyl carbinols. The electrochemistry of the reactions is to be studied.

The Invention of the Sewing Machine

ON Mar 8, M Herriott, the former premier of France, unveiled a monument at Lyons to Barthélemy Thimonnier, the inventor of the sewing machine Thimonnier applied for his first patent in collaboration with Auguste Ferrand of the School of Mines, St Étienne, on April 12, 1830, and the erection of the monument was the outcome of the celebration last year of the centenary of that event The commemoration which took place in Paris in May last included meetings in the Conservatoire national des Arts et Métiers, the Sorbonne, and elsewhere, a record of which is contained in the February *Bulletin de la Société d'Encouragement pour l'Industrie nationale*, which also contains a biographical sketch of Thimonnier by M Am Matagrin, of Lyons

Born at l'Arbresle, in the department of the Rhône, on Aug 19, 1793 Thimonnier attended school in Lyons and after an apprenticeship set up as a journeyman tailor at Amplepuis where he first conceived the idea of sewing by machinery Removing in 1825 to St Étienne, he lived in the rue des Forges, where he made a sewing machine and, with the assistance of Ferrand and others, not only secured a patent, but also in the summer of 1830 formed a company in Paris for the construction of machines By 1831, no fewer than eighty machines had been made, but a mob destroyed them all and for a time nothing more was done Thimonnier, however, continued all his life to devote much time to his invention, taking out other patents, and with Magnin forming another company but without reaping any adequate rewards He died a poor man, on Aug 5, 1857 The sewing machine by then had claimed the attention of many other inventors, but at the Paris Exhibition of 1855, Prof Willis, of Cambridge, reporting on the machines exhibited, said that Thimonnier's machine had served as a type for all modern sewing machines

Thimonnier's sewing machine was a chain stitch or single thread machine, in which the needle, having a notch near the point, left a loop beneath the material, through which the next stitch passed, but the machines developed by subsequent inventors were lock stitch machines, in which one thread is fed by the needle, which has an eye, and another thread is fed by a shuttle Thousands of patents have been taken out in connexion with such machines, but it was the work first of Elias Howe and then of Isaac Merritt Singer in the United States which brought the sewing machine into general use and provided the people of every nation with a simple, reliable machine at a reasonable price

There was a great deal of litigation between the early inventors, and the example of a Thimonnier machine in the Science Museum was one used during the trials in the United States If to Thimonnier the invention brought nothing but disappointment and anxiety, others were more fortunate, and Howe and Singer both amassed great wealth Though he died, as he lived, a simple working man Thimonnier to-day is remembered as a benefactor of his country, and the tablet marking the site of his house in St Étienne and the monument at Lyons will for a long time recall his gallant struggle against adverse conditions

The Climate of Sweden.*

SWEDEN lies in the region of prevailing south westerly winds that blow along the margin of the nearly permanent area of low barometric pressure centred near Iceland It appears from certain wind roses given on pages 52 and 53 of Axel Wallén's work, that it is only in the south—in Götaland—that there is a general predominance of south westerly winds in the surface layers of the atmosphere approaching that which is to be found in the British Isles Elsewhere, effects due to the distribution of land and water, and to the contours of the land, modify the general drift from the dominant quarter Thus, along the eastern coast, both in January and July, the wind tends to follow the trend of the coast line and therefore blows most frequently from southerly or northerly directions

The mountains that cover so large a part of Scandinavia greatly alter the effects of the moist Atlantic winds on the Swedish climate In the absence of such mountains, the climate would probably more nearly resemble that of Denmark there would not be the great contrasts that exist between the very wet western uplands and the dry eastern coastal region The heavy precipitation in the west leaves so much less moisture for cloud formation when the winds of the troposphere follow their usual course towards Finland and Russia, this is one of the factors that makes possible the wonderfully sunny summer climate of the eastern lowlands and of the islands off the east coast Students of British weather are familiar with this drying process, which acts powerfully in eastern Scotland and north east England during spells of westerly wind These general facts come to light in the course of a careful reading of Axel Wallén's work, but there is perhaps a tendency for a rather too rigid separation of the climatic factors This tendency makes it harder for the reader to get a grip of the broad facts of Swedish climatology, and to remember them, than would otherwise have been the case, the absence of an index and table of contents increases the reader's difficulties

On the whole, the manner in which the different sections are handled is orthodox More than usual attention is given to hydrology and matters of practical importance for the economic use of the abundant potential energy of the heavy rain and snow of the mountainous regions The snowfall is of use not only as a supply of water when it melts, but also, when lying, for the transport of felled timber by sledge to the commercial waterways The seasonal and annual variations of the total rainfall have their usual importance, in so far as they affect the flow of water in the rivers Sweden's extensive lakes, which occupy more than 8 per cent of the whole country, act as reservoirs capable of storing the surplus of an extra wet season It is not inappropriate in the case of a country so dependent economically upon the potential energy of rainfall to find that these various matters occupy 30 per cent of the space devoted to a discussion of climate There is a very instructive map (p 61) to which the reader's attention may be directed This shows the distribution throughout Sweden of water power, in kilowatts per square kilometre, for average conditions of waterflow

Readers of this work who are not familiar with the physical and other features of Sweden will appreciate the very clear maps among the first few pages These show the major and minor political divisions, the contours, the distribution of the different types of forest, facts relating to the late glacial epoch, and

* The Climate of Sweden By Axel Wallén Statens Meteorologisk Hydrografiska Anstalt Nr 270 B 65 (Stockholm, 1930) 2 00 kr

details of the principal river basins Another excellent point is the inclusion of a short discussion on inward and outward radiation This subject ought not to be neglected in the discussion of any climate and least of all in the case of one referring to a country placed in such high latitudes as to show very great seasonal contrasts In the extreme north of Sweden (lat 69°) the sun is never less than 2° below the horizon in the middle of the winter Even in the south (lat 56°) the solar elevation at that season does not exceed $10\frac{1}{2}°$ In the middle of the summer, on the other hand, a large part of Sweden enjoys perpetual daylight In the early summer, the average amount of cloud in the eastern lowlands falls below anything known in Great Britain and, in the islands off the east coast, reaches the low figure of 40 per cent in June When the long day is considered in relation to these facts no surprise will be caused by the statement (p 12) that the mean duration of sunshine at Jokkmokk (lat 66° 36′) in June exceeds that of Madrid or Rome in the same month In sympathy with the large annual variation of solar radiation, temperature shows great seasonal contrasts At Karesuands (lat 68° 27′) the mean temperature for July is about 28° C (50° F) higher than that for January

Figs 6 and 7 are among the most interesting in the book The former gives graphs of the radiation received at the outer limit of the atmosphere in each month in latitudes 55°, 60 65°, and 70°, similar graphs showing how much of this reaches the earth's surface when the sky is free from cloud, a graph of the radiation actually received at Stockholm, taking into consideration the amount of cloud, is also shown In Fig 7 this graph of inward radiation at the ground for Stockholm is compared with that of outward radiation at the same place The outward radiation has of course, much the smaller annual variation The comparison shows that from the beginning of October to the end of March the outward exceeds the inward radiation, and that the reverse is true during the rest of the year On the whole year it would appear that there is a gain The reader may be referred to recent papers by Dr G C Simpson Director of the Meteorological Office of Great Britain, for a more general discussion of this subject, which is by no means free from pitfalls

E V NEWNHAM

Afforestation Programmes of the New Zealand Forest Department

IN a recent number of NATURE (Feb 14, p 255) attention was directed to the organisation known as the New Zealand Timber Growers' Association, of New Zealand This body consists of a series of independent private companies engaged in afforestation work as a purely commercial proposition, with funds subscribed by the public on ordinary share issue terms These companies have no connexion with the official New Zealand Forest Department but it is already apparent that they will eventually own by far the largest area of artificially formed plantations in the islands Contrasted with the operations of these companies, already discussed in the note referred to, the Annual Report of the Director of the N Z State Forest presents the Government forestry position which is equally satisfactory On the subject of afforestation work the Report states "New Zealand possesses the largest area of State owned and State planted forests in the Empire The State owned indigenous forests as at March 31st, 1930, consisted of over 7 million acres The State Softwood Plantations, in round figures, at the same date, covered 253,600 acres The total area planted during the 12 months prior to the date mentioned was 56,630 acres For the current year a further 54,629 acres was programmed for, which would bring the total of New Zealand s State Softwood Plantations at this present date to a figure approximating 308,000 acres In the year ended March 31st, 1929, the State planted 60,635 acres altogether"

A contrast is then made with similar work in Great Britain The Forestry Commission in England, it is pointed out, planted to the end of 1929, 140,000 acres of softwoods, "while the planting programme is 23,000 acres per annum, so that New Zealand is well ahead of the Mother Country, and furthermore would be justified at the present time in claiming world leadership in annual softwood plantings under the State" Full credit may be given to the New Zealand authorities for the efficient manner in which they are dealing with this problem, but any attempt at rivalry in the rate of afforestation or in programmes with that sole end in view between the Dominion and Great Britain is most strongly to be deprecated Many things must govern annual planting programmes, and the delicate and important operations of thinning, once the young woods have reached the size for these operations, annually increase in amount and demand the closest attention Too often in the past have annual afforestation programmes been pressed on, to the neglect of the necessary thinning work in the young created woods, for which either the funds or the necessary labour were deficient or absent

The commercial planting companies have planted a total area of about 220 000 acres, the species being *Pinus insignis*, redwoods, *Pinus ponderosa*, and poplar Thus State plantings plus the planting of these afforestation companies now total approximately 500 000 acres, last year s total plantings being somewhere in the region of 100 000 acres

Since the commercial planting companies are wholeheartedly devoting themselves to new afforestation work it will be hoped that the Government Department is not losing sight of the important indigenous forests There may be quite valid reasons for embarking upon a large programme of plantations of exotics in a country—in parts of our Empire we know that such valid reasons exist—but all experienced foresters hold strongly to the belief that in the long run few exotic plantations can compete in value with the indigenous forest of a country

It is a well established fact that the planting of large blocks of exotics often as pure woods, leads to the danger of attacks of pests whether insect or fungus This factor has not been overlooked in New Zealand Research work in forest biology has been placed on a good basis by the linking up of the research forces of the State Forest Service the Department of Scientific and Industrial Research, and the New Zealand Timber Growers' Association, under the direction of Dr David Miller, with whom is associated Dr Marsden A number of research stations under the ægis of the State Forest Service have been established throughout the Dominion, the forestry schools of the University of New Zealand making contributions to the scientific side of afforestation Amongst studies on the commercial side of forestry, investigations into the strength of structural timbers are being carried out, and an extensive economic pulpwood survey is in progress with the object of establishing pulp and paper mills in promising localities

It is of interest to note that Australia continues to absorb practically the whole of the timber exports of New Zealand, but, the Report says, "enquiries from the United Kingdom continue to increase"

University and Educational Intelligence

London Applications for grants from the Dixon Fund, for assistance in scientific investigations, must be received before May 15 by the Academic Registrar, University of London, South Kensington, S W 7 Those for grants from the Thomas Smythe Hughes Fund, for assistance in medical research, must be received by the Academic Registrar not later than May 15

Oxford The recommendations of the committee appointed to consider and report on the provision of library facilities in Oxford have been embodied in a decree to be promulgated in Congregation on May 7 The recommendations include, as already noticed in Nature of Mar 28, p 493, the enlargement of the Radcliffe Scientific Library by the addition of a new wing

St Andrews —The Senatus Academicus will confer the honorary degree of LL D on the following, among others, on June 26 Sir James Hopwood Jeans, Dr G M Robertson, professor of psychiatry in the University of Edinburgh, Rev Alfred Young, formerly fellow of Clare College, Cambridge, rector of the parish of Birdbrook, Halstead, Essex, distinguished for his mathematical work

Under the will of the late Mr John McMaster, of Harbledown, near Canterbury, who died on Feb 10, the Ayrshire Education Authority will receive £300 a year for the establishment and maintenance of bursaries or scholarships to be known as "John McMaster Bursaries", tenable at the Universities of Edinburgh or Glasgow, and open to boys educated at Girvan Secondary School whose parents are in necessitous circumstances, and the Governors of Simon Langton Boys' School, Canterbury, £350 a year for the establishment and maintenance of scholarships to be known as "John McMaster Scholarships", tenable at the Universities of Oxford, Cambridge, Edinburgh, or London, to be awarded to boys of that school

The Educational Travel Association is arranging a summer holiday course in the methods of regional survey and in open air geography, in Norway The fiords, the subarctic tableland, and the eastern valleys round Oslo will be visited The party will sail from Newcastle on Aug 8 Particulars of the itinerary may be obtained by sending a 2d stamp to the honorary secretary, E T A, "Noddfa", Wistaston, Crewe (or, c/o Cheshire Training College, Crewe), who will supply an illustrated booklet and map, and a programme of excursions to glaciers and various land forms, as well as to the Norwegian open air museum, Viking ships, and Amundsen's unique collection of Eskimo tools, clothing, and kayaks Instruction in field work in the open air sciences will be given to members of the party desiring it

The League of Nations Union, in co operation with the American School Citizenship League, has again arranged a prize essay competition open to both British and American schools Prizes of 75 dollars, 50 dollars, and 25 dollars, known as the Seabury Prizes, are offered for the best essays in each of the following sections (1) Open to all pupils in public and secondary schools in the British Isles, on "What Subjects in the School Curriculum are Best Adapted to Show the Interdependence of Peoples?", and (2) open to all students in teachers' training colleges and university training departments, on "The Influence of Intellectual Co operation in the Promotion of World Friendship" Essays, which must not exceed 3000 words and must be written on one side only of paper with a margin of at least one inch, must reach the League of Nations Union, 15 Grosvenor Crescent, S W 1, not later than July 1 and should bear the writer's name, age, school, and home address

A list of international fellowships for research, compiled by the International Federation of University Women and published in pamphlet form, gives particulars of many hundreds of stipends available for advanced study and research in countries other than the stipend-holder's own The first and largest section relates to fellowships available only to nationals of one country Among other interesting items in this section are 42 American German exchange scholarships and about 170 Hungarian scholarships tenable in Vienna (40 to 56), Rome (40 to 46), Berlin (35) Great Britain (14), and elsewhere Great Britain's place in this section is a large one and so is Sweden's Section II contains fellowships open to students from more than one country or irrespective of nationality These are almost exclusively provided from British and American sources Appended is a list of nineteen *prizes open for international competition* Copies of the pamphlet can be obtained, price 1*s* 3*d* post free, from the British Federation of University Women, Crosby Hall, Cheyne Walk, London, S W 3

Birthdays and Research Centres

April 11, 1863 — Mr Henry Balfour, F R S, curator of the Pitt Rivers Museum, Oxford

I am at present investigating the stone implements of the Tasmanians, their technique and the culture status which they suggest

The scientific classification of primitive musical instruments and the determination of the geographical dispersal of related and analogous types would be a useful undertaking Primary classification must be based upon the exact method or mechanism whereby the sound is initiated, the means whereby the notes *may be varied being of secondary importance* In the new edition (fifth) of "Notes and Queries on Anthropology", pp 295 308, I have suggested a scheme of primary grouping, as an aid to descriptions and diagnosis of types of instruments Accurate description of the various means adopted for the production of the vibrations causing sound are required, in order to arrive at a satisfactory phylogenetic classification of musical instruments, and to enable the distribution of particular types to be mapped out

April 23, 1858 —Prof Max Planck, For Mem R S, professor of mathematical physics in the University of Berlin

Die theoretische Physik ist durch die Quantentheorie etwas in Unordnung geraten Sicher ist, dass von den bisher allgemein angenommenen Grundsätzen mindestens einer geopfert werden muss, um die übrigen aufrecht erhalten zu können Dies vollkommen klarzustellen ist eine der wichtigsten Aufgaben der nächsten Forschung Soweit ich sehe, gehört zu den Sätzen, welche unter allen Umständen beizubehalten sind, die Voraussetzung einer volkommenen Gesetzmässigkeit in allen physikalischen Vorgängen; dagegen zu denjenigen, welche fallen gelassen werden müssen, die Voraussetzung, dass der gesetzliche Ablauf eines Vorgangs dargestellt werden kann mittelst einer Zerlegung desselben in seine räumlichen und zeitlichen Elemente Es ist also der Begriff der Ganzheit, der wie auf dem Gebiet der Biologie so auch auf dem der Physik eingeführt werden muss, um die Gesetzlichkeit der Natur verstehen und formulieren zu können.

Societies and Academies.

LONDON

Geological Society, Mar 18.—O H Schindewolf, On the septal development and the genotype of the coral genus *Petraia* Munster The author, by showing that the genotype of *Petraia* is a synonym of *Petraia radiata* Munster, restricts the name to the Upper Silurian species The Devonian species belong to Počta's genus *Alleynia* *Petraia*, which is well characterised by its conical shape, deep calice, external ornamentation, arrangement of the septa, and, in normal specimens, by the absence of transverse tissue, has not been found outside Bavaria W B R King A fossiliferous limestone associated with Ingletonian Beds at Horton in Ribblesdale, Yorkshire The paper deals with an exposure of green felspathic grits with associated calcareous rocks in the railway cutting south of Horton in Ribblesdale station The problems of general stratigraphy are discussed There is much evidence of a general nature to suggest that although the limestone is undoubtedly of Ashgillian age, the grits with which it is associated must be considerably older Calcareous matter occurs in two forms in the cutting, first, as the infilling between the grit blocks of a breccia, and secondly, as a crystalline fossiliferous limestone apparently interbedded with the grits A detailed study of the limestone, however, shows that it is essentially of the same origin as the calcareous part of the breccia, since it contains angular fragments of grit and occasional flakes of roughly cleaved green mudstone of a type exactly like the Ingletonian of the neighbourhood The fossils show no signs of distortion by cleavage It is suggested that this is another case of a 'Neptunian dyke'

Linnean Society, Mar 19.—M Bernhauer and H Scott Abyssinian Staphylinidæ systematic report and introduction, with biogeographical and ecological remarks Dr Bernhauer enumerates 123 species, only 11 of which had been recorded from Abyssinia before, while 56 are new to science The affinities of the Staphylinidæ under review are mainly African, but there is a small proportion of Palæarctic species or related forms Among many kinds of environment, special attention was paid to dead stems of tree Euphorbias (*Euphorbia abyssinica*) and of tree Lobelias (*Lobelia Rhynchopetalum*), and species apparently peculiar to these habitats were found

Society of Public Analysts, April 1.—R C Frederick Carbon monoxide poisoning its detection and the determination of the percentage saturation in blood, by means of the Hartridge reversion spectroscope The instrument is capable of giving a quantitative determination of very small percentages of carbon dioxide in a minute quantity of blood The author has been unable to confirm Haldane's conclusions on nitrogen monoxide hæmoglobin, the reversion spectroscope showing that the nitrogen monoxide hæmoglobin spectrum is quite different from that of carbon monoxide hæmoglobin.—H M Mason and G Walsh Experiments on the hardness of fats A simple apparatus has been devised in which the weight required to drive a plunger into the solid cake of fat of standard thickness under standard conditions is measured The results of the hardness test have also been used to establish the identity of fats and to detect adulteration.—B S Evans A new process for the determination of small amounts of bromide in chloride Bromides are rapidly and completely oxidised by chromic acid in the presence of sulphuric acid, preferably of 8-9 N strength, whilst chlorides remain untouched The liberated bromine is conveyed by means of a current of air into an absorption flask containing standard arsenious oxide solution and some sodium bicarbonate, and the excess of arsenious acid is titrated with standard iodine For determining small percentages of bromides in chlorides, the bromine is first absorbed in a tube containing 0.5 per cent sodium hydroxide solution, and this solution is then treated with one or two drops of saturated sulphur dioxide solution, then with dilute sulphuric acid and chromic acid, and the determination completed as described.—S G Walton and R G O'Brien The use of bromine as a reagent in the determination of alkaloids The thalleioquin reaction for quinine has been made quantitative the excess of bromine being removed by aeration, and the coloration compared with that given by standard solutions An iodometric development of the method enables quinine to be determined in the presence of other alkaloids The bromine compounds of morphine and most of the other opium alkaloids liberate iodine from potassium iodide, and methods of determination are based on the reactions Codeine may be determined colorimetrically by measuring the depth of the red colour formed on oxidising its bromine compound with hydrogen peroxide Colorimetric methods have also been devised for the ipecacuanha alkaloids, based on the yellow coloration formed on aerating the bromine compounds

DUBLIN

Royal Irish Academy, Feb 23.—T J Nolan and M T Casey Further studies in the pigment of the berry of the elder (*Sambucus nigra*) From the berry of the elder, two anthocyan pigments have been isolated in crystalline form as chlorides One of these is identical with chrysanthemin, the pigment of the dark red garden chrysanthemum The second pigment, sambucicyanin, which crystallises in long prisms, is, according to analysis, a bi molecular compound of chrysanthemin with a pentose-glucoside of cyanidin The two pigments are similar in their colour reactions, but sambucicyanin is more soluble in hydrochloric acid and in alcohol than chrysanthemin No methyl pentose glucosides were isolated, and the authors are unable to confirm the observation of Karrer and Widmer that a rhamnoglucoside is present in the berry

Royal Dublin Society Mar 24.—W R G Atkins Observations on the photoelectric measurement of the radiation from mercury vapour lamps and from the sun, and on the effects of such radiation on the skin A vacuum sodium photoelectric cell, made of glass, and selective screens were used to study the radiation from a Hewettic Levick Ulviarc mercury vapour arc used for clinical work It is generally advisable to run the arc continuously between treatments, as the maximum illumination is not reached until 6 min after the lamp has been switched on A subsequent slow decline is attributed to gradual over heating, to counteract which the lamp should be switched off for a minute or two after 35-40 min, 5 min after switching on again the original maximum is recovered Irregular fluctuations in the light of the arc do not seem to be caused by cooling due to draughts, and are probably due to variations in the supply voltage The radiation from a lamp which had been in use 750 hours, and had been discarded as uneconomical of time for clinical work, was found to be 40 per cent for the blue, violet, and ultra violet, 36 per cent for the ultra violet, and 24 per cent for the anti rachitic ultra violet, as compared with a new lamp The new

lamp may produce slight erythema in 1 minute and definite erythema in 2 min at a distance of 60 cm Noon sunlight (93,000 metre candles on the potassium carbon arc scale) produces some effect in 10 min and definite erythema in 30 min Beck's ultra violet fluorescence spectroscope was useful for qualitative observations Approximate photoelectric determinations of the ultra violet light in daylight showed that in this respect, even at mid summer noon, the direct sunlight is not very much more potent than the diffuse light from the sky

PARIS

Academy of Sciences, Mar 2 — **H Deslandres** Simple relations of molecular spectra with the structure of the molecule — **Gabriel Bertrand** and **Mme Georgette Lévy** The amount of aluminium in plants, especially those utilised as food The proportions of aluminium found in a large number of edible roots, tubercles, seeds, and leaves are given — **Jean Effront** The fall in the rotatory power of solutions of glucides under the action of alkalis — Charles Jacob was elected a member of the Section of Mineralogy, in succession to the late P Termier **Pasquier** The equations $s = f(x, y, z, p, q)$ integrable by the Darboux method **J Schreier** and **St M Ulam** A property of the unit of Lebesgue — **A Lokchine** The rotating vibrations of a body limited by a surface of revolution — **Henri Poncin** The possible permanent movements of a heavy fluid — **B Hostinsky** The theory of diffusion — **A Sesmat** A new hypothesis on radiation and on the optics of bodies in motion — **Pierre Lejay** An arrangement allowing the amplification of weak photoelectric currents and its application to recording the light flux proceeding from the stars The apparatus described in an earlier communication, utilising ordinary amplifying valves as electrometers, has been improved by the addition of a new type of valve In combination with a photoelectric cell and a recording oscillograph, the apparatus can be used to record the passage of a star in meridian observations, or to measure intensities, as a recording photometer — **Clerget** Apparatus for observing the phenomena of injection in compressed air **Georges Fournier** and **Marcel Guillot** The absorption of the β rays by matter The same absorption coefficients were found for liquid and solid white phosphorus, but there appeared to be a slight difference between the absorption coefficients of the two allotropic forms of phosphorus — **F Bourion** and **E Rouyer** The cryoscopic study of paraldehyde in solutions of calcium and strontium chlorides — **J J Trillat** and **J Forestier** The structure of plastic sulphur Threads of plastic sulphur, pulled out immediately after formation, become less transparent, lose their elasticity, and give a much higher breaking load increasing from 70 gm to 9 or 10 kgm per sq mm The threads, which were amorphous before stretching, behave as crystalline fibres X rays increase the rate of crystallisation of plastic sulphur — **A Mailhe** and **Renaudie** The catalytic condensation of the amylenes Heated to 670°, in presence of silica gel, the amylenes give gases (unsaturated hydrocarbons, methane, hydrogen) and a mixture of liquid unsaturated and aromatic hydrocarbons Benzene, toluene, and xylene were definitely identified — **Charles Dufraisse** and **Raymond Horclois** The application of the antioxygen effect to the problem of fire extinguishing The negative catalysis of the ignition of carbon As with low temperature oxidations, ignition can be hindered by negative catalysts **A Grebel** The process of combustion of pulverised coal — **Conrad Kilian** The genesis of the Central Sahara Massif — **Henri Termier** The discordances in the palæozoic series of Central Morocco — **G Garde** The old course of the Allier and its affluents on the Gannat during the Upper Pliocene and Quaternary — **A Demay** The prolongation of the Cevenol tectonic complex in the Louvesc mountains — **Guilliermond** The conjugation of the ascospores in the yeasts and some obscure points in the development of these fungi — **Mlle Cassaigne** The origin of vacuoles In most cases, the vacuoles arise spontaneously in the cytoplasm, but they can also be produced by the drawing out and breaking up of preformed vacuoles, phenomena which appear to be determined by the movements of the cytoplasm — **Gustave Jaquenaud** The influence of the nature of the soil and of radiations on the degenerescence of the potato — **J Nageotte** The variations of the sign of double refraction in myelinic figures and connected formations — **H Simonnet** and **G Tanret** The calcifying action and the toxic action in the animal of large doses of irradiated ergosterol an attempt to separate those two actions It is established that the irradiation products of ergosterol contain two distinct factors, one toxic the other calcifying The calcification is much reduced when small doses of potassium iodide are administered along with the irradiated ergosterol

ROME

Royal National Academy of the Lincei Communications received during the vacation, 1930 — **G Castelnuovo** De Sitter's universe — **L Rolla** Experiments on the concentration and isolation of the element of atomic number 61 Fractionation of the rare earths obtained from monazite sand, and spectroscopic examination of the different fractions, has failed to produce evidence of the presence of the element of atomic number 61 — **G Barba** Absolute geodetics of surfaces — **B de Finetti** Characteristic functions of instantaneous laws — **Luisa Pelosi** Mean curvature of surfaces The new expression recently evolved by Calonghi for the mean curvature of a surface may be derived by a more rapid and simple calculation — **E Čech** Further considerations on Cauchy's theorem — **S Amante** Resolution, in the field of complex matrices, of any analytical equation with numerical coefficients — **L Fantappiè** Maxima and minima of real analytical functionals — **S Finikoff** The congruence R having two 'gauche' surfaces for the two folds of its focal surface — **E Gugino** The dynamic problem of any linked system reduced to the analogous problem relating to a free system — **A Signorini** The finite deformations of continuous systems An introduction, purely kinematic in character, is given to a summary of various studies on the finite deformations of continuous systems with reversible transformations, especially on those of elastic systems — **Angelina Cabras** Rigid motions in generalised spaces — **A Masotti** Rectilinear vortex in a channel with plane parallel sides — **A Fresa** Variations of the light of the variable RZ Cassiopeiæ Investigation of the light curve of this variable reveals the existence of a well defined secondary minimum in the neighbourhood of the maximum preceding the principal minimum, of a slight inflexion, possibly periodic, of the light curve on the descending branch, and of an increase of 0 86 second in the period of the variable — **Seb Timpanaro** Waves and corpuscles — **D Graffi** Considerations on the theory of the transmission of heat by forced convexion (2) From the theorem of unicity established in the previous note on this subject, a principle of superposition of effects is developed — **A Quilico** The oxidation of propenyl derivatives by means of diazo compounds The mechanism recently suggested by Angeli and Polverini for the oxidation of propenyl compounds by diazohydrates is discussed and evidence advanced in sup-

port of it —Clara Forti The excision of the vessels and nerves of the ovary total or partial excision and sexual functions (2) Experiments with rats show that the excision of ovarian vessels and nerves does not markedly disturb, even after several months, the sexual cycle Excision of the nervo-vascular fibre of the ovary and uterus does, however, cause serious and persistent alterations in the sexual functions

FRIDAY, APRIL 17

INSTITUTION OF MUNICIPAL AND COUNTY ENGINEERS (North Western District) (at Victoria Station, Manchester) at 9 30 A M

BRITISH INSTITUTE OF RADIOLOGY (at North Middlesex Hospital, Edmonton), at 11 A.M.—At 5 —Meeting of Medical Members

ELECTRICAL ASSOCIATION FOR WOMEN (at Park Lane Hotel) at 11 30 A.M —Annual General Meeting —At 3 — Report from Branches, etc

LONDON SOCIETY (at Royal Society of Arts), at 5 —Dr D McKenzie Noise—a Modern Plague of London

SOCIETY OF MEDICAL OFFICERS OF HEALTH (at 1 Upper Montague Street, W C), at 5 —Dr Ethel Cassie, Dr G C M M'Gonigle, and others Discussion on the Pre school Child

PHYSICAL SOCIETY (at Imperial College of Science and Technology), at 5 —A J Maddock The Generation of Current Pulses of Rectangular Wave form —R A Fereday An Improved Method for the Comparison of Small Magnetic Susceptibilities —Dr E G Richardson Edge Tones

NATIONAL INSTITUTE OF INDUSTRIAL PSYCHOLOGY (Annual General Meeting) (at Royal Society), at 5

ROYAL SANITARY INSTITUTE (at Guildhall, Poole), at 5 —E J Goodacre and others Discussion on Some Aspects of Municipal Sanitation — Alderman J C Julyan and others Discussion on Prospect and Retrospect.—Dr G Chesney and others Discussion on Diphtheria Immunisation at Work

ROYAL SOCIETY OF MEDICINE (Clinical Section), at 5 30

INSTITUTION OF MECHANICAL ENGINEERS, at 6 —C D Gibb Post War Land Turbine Development

NORTH EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (at Mining Institute, Newcastle upon Tyne), at 6.—J Foster King Corrosion of Oil Tankers

COKE OVEN MANAGERS ASSOCIATION (Midland Section) (at Sheffield University), at 6 30 —Prof R V Wheeler Rational Analysis of Coal

SOCIETY OF DYERS AND COLOURISTS (Manchester Section) (at 36 George Street, Manchester), at 7 – Annual Meeting

INSTITUTION OF ELECTRICAL ENGINEERS (Meter and Instrument Section) at 7 —E W Hill and G F Shotter Current Transformer Summations

INSTITUTE OF FUEL (East Midlands Section) (at University College, Nottingham), at 7 —H L Pirie Theory and Practice of the Gasification of Coal in Producers

SOCIETY OF CHEMICAL INDUSTRY (Newcastle Section) (at Armstrong College Newcastle upon Tyne) (Annual Meeting), at 7 30.—Demonstration of Modern Scientific Instruments and Apparatus of Special Interest

INSTITUTE OF METALS (Sheffield Section) (in Non Ferrous Section of Applied Science Department, University of Sheffield), at 7 30 —R Genders Extrusion

JUNIOR INSTITUTION OF ENGINEERS at 7 30 —J E Gray The Transmission of Gas.– T G Martin The Building Requirements of Lifts

ROYAL SOCIETY OF MEDICINE (Electro Therapeutics Section) at 8 30 — Dr J C Mottram Secondary Radiation in Bone —Dr J Halliwell Pyelography – Dr C A Robinson Backache in its Relation to Cervicitis, and its Treatment by Diathermy

INSTITUTE OF BREWING (Yorkshire and North Eastern Section) (at Queen s Hotel Leeds) —Annual Meeting

SATURDAY, APRIL 18

INSTITUTION OF MUNICIPAL AND COUNTY ENGINEERS (Yorkshire District) (at Sowerby Bridge) at 2

MINING INSTITUTE OF SCOTLAND (at Royal Technical College Glasgow) at 3 —Annual General Meeting

MONDAY, APRIL 20

INSTITUTION OF ELECTRICAL ENGINEERS (Informal Meeting), at 7 — Alderman R Tweedy Smith and others Discussion on Everyday Commercial Risks of and Liabilities to Engineers

BRITISH KINEMATOGRAPH SOCIETY (at Film House Wardour Street), at 7 45 —J Ree The Fidelytone Sound Recording System

ROYAL SOCIETY OF ARTS, at 8 —Dr N A V Piercy The Present Position in Aeronautics (Howard Lectures) (2).

ROYAL GEOGRAPHICAL SOCIETY at 8 30 —Major R. A Bagnold Journeys in the Libyan Desert 1929 and 1930

ROYAL SOCIETY OF MEDICINE at 9 15 —Dr C Wilson Some Aspects of Alpine Climbing

TUESDAY APRIL 21

ROYAL SOCIETY OF MEDICINE, at 5 30 – General Meeting

INSTITUTE OF FUEL (North Western Section) (at 17 Albert Square, Manchester) (Annual General Meeting), at 7 —C A Seyler Fuel Technology and the Classification of Coal

ILLUMINATING ENGINEERING SOCIETY (at Royal Society of Arts), at 7 30 —W G Mackenzie Some Aspects of Street Lighting in the United States

WEDNESDAY, APRIL 22

GEOLOGICAL SOCIETY OF LONDON at 5 30.—Dr H H Thomas and W Campbell Smith Xenoliths of Igneous Origin in the Trégastel Ploumanac h Granite Côtes-du Nord France —C I Gardiner and Prof S H Reynolds The Loch Doon Granite Area Galloway

SOCIETY OF CHEMICAL INDUSTRY (jointly with British Association of Chemists and Institute of Chemistry) (at Technical College, Derby), at 7 —Dr A Bramley Diffusion in Solids

ROYAL SOCIETY OF ARTS, at 8.—Prof Major Greenwood The Work of the London School of Hygiene and Tropical Medicine followed by a demonstration by Prof J G Thomson of a Malaria Film

BRITISH PSYCHOLOGICAL SOCIETY (Medical Section) (at Medical Society of London) at 8 30 —Dr H V Dicks A Clinical Study of Obsession

THURSDAY, APRIL 23

LONDON MATHEMATICAL SOCIETY (at Royal Astronomical Society), at 5 — Discussion on Recent Work in the Additive Theory of Numbers, to be opened by Prof G H Hardy, followed by E Maitland Wright New Partition Problems —A. E Ingham The Method of Brun and the Theorem of Schnirelmann —Dr A E Western Computative Work Connected with Waring s Problem —Other speakers Prof L J Mordell, S. D Chowla, Dr T Estermann, and Prof J E Littlewood

COKE OVEN MANAGERS ASSOCIATION (Northern Section) (at Three Tuns Hotel Durham) —Discussion

FRIDAY, APRIL 24

ROYAL SOCIETY OF ARTS (Indian Meeting), at 4 30 —Sir William Foster John Zoffany in India

ROYAL SOCIETY OF MEDICINE (Disease in Children Section) (at Westminster Hospital) at 4 30

INSTITUTE OF MARINE ENGINEERS, at 6 —Annual General Meeting

INSTITUTION OF MECHANICAL ENGINEERS, at 6 —Sixth Report of the Marine Oil Engine Trials Committee

INSTITUTION OF ELECTRICAL ENGINEERS (London Students Section), at 6.15 —J Dunbar The Design and Manufacture of Electrical Apparatus

SOCIETY OF CHEMICAL INDUSTRY (Chemical Engineering Group) (Annual General Meeting) (at Waldorf Hotel Aldwych), at 6 45 —At 7 30 —Sir Richard Gregory, Bart. Science in Industry

BRITISH ASSOCIATION OF CHEMISTS (Scottish Section) (at Central Halls, Glasgow), at 7 30 —Annual General Meeting

ROYAL INSTITUTION OF GREAT BRITAIN, at 9 —Sir Philip Hartog Joseph Priestley and his Place in the History of Science

SATURDAY, APRIL 25

NORTH OF ENGLAND INSTITUTE OF MINING AND MECHANICAL ENGINEERS, at 2.30

PUBLIC LECTURE.

TUESDAY, APRIL 21

GRESHAM COLLEGE at 6 —W H Wagstaff Geometry (Succeeding Lectures on April 22, 23 and 24)

DISCUSSION.

APRIL 17 AND 18

GENERAL DISCUSSION ON PHOTOCHEMICAL PROCESSES.

FARADAY SOCIETY (in Department of Chemistry Liverpool University)

Friday, April 17, at 10 A M —Molecular Spectra in Relation to Photochemical Change

Introductory Paper Prof R Mecke

Ultra violet Absorption Spectra of Acetylene and Formaldehyde Dr G Herzberg

The Absorption Spectra and the Optical Dissociation of the Hydrides of the Oxygen Group C F Goodeve and N O Stein

The Photochemical Properties of the Carbonyl Group F W Kirkbride and R G W Norrish

Friday, April 17, at 2 30 —Photochemical Kinetics in Gaseous Systems

Introductory Paper Prof M Bodenstein

The Reaction between H_2 and O_2 under the Influence of Photochemically produced H Atoms. The Relation of its Mechanism with that of the Explosive Gas Reaction at High Temperatures. Dr W Frankenburger

The Photochemical Union of Hydrogen and Chlorine at Low Pressures I B Bateman and H C Craggs.

The Photosensitised Decomposition of Nitrogen Trichloride by Chlorine, and the Induction Period of the Hydrogen Chlorine Reaction J G A. Griffiths and R G W Norrish

The Photosensitised Formation of Hydrogen Peroxide in the System Hydrogen Oxygen Chlorine R G W Norrish

The Photochemistry of Mixtures of Chlorine Oxygen and Carbon Monoxide Prof G K. Rollefson

The Mechanism of the Photo Oxidation of Gaseous Alkyl Halides J R Bates and R Spence

A Comparison of the Efficiency of Photochemical Reactions and Similar Reactions Produced by Gaseous Ions G R Gedye

The Loss of the Airship *R101*.*

THE Report of the *R101* Inquiry, to which reference was made in NATURE of April 11, represents the unanimous finding of Sir John Simon and his two assessors, Lieut-Col J T C Moore Brabazon and Prof C E Inglis It is a remarkable document, in that it contains probably all the available relevant knowledge of the various phases of airship work, culled from a variety of sources, and presented in the form of a logical and reasoned argument that bears the obvious imprint of Sir John Simon's unbiased legal mind The witnesses called before the court were, roughly, of three types, namely, those professionally concerned with the design and construction of the airship, who dealt with their own specialities, eyewitnesses of the disaster, mostly non-technical, whose evidence served to confirm or disprove certain theories, and other airship experts who came forward with suggestions of their own to assist the court These matters are dealt with in one part of the Report Another section is devoted to the question of assessing the responsibility for the existence of the general state of affairs that led to the undertaking of the flight to India at that time

The court, in justification of the conclusions of its Report, says

"In discussing the cause of the accident, one starts with a series of definitely ascertained facts It is then possible to exclude, by a process of reasoning which appears conclusive, certain suggested explanations which need to be examined before they can be rejected In the result, the analysis indicates, with some degree of confidence, the general nature of the true cause, though precise detail can never be attained, since no one who was in the control car has survived"

The final movements of the ship leading to the crash can be, it is suggested, divided into three phases First, the ship, while in a deliberate downward pointed attitude correcting an upward deviation, was caught by a down current, and descended through a steep angle for about half a minute, thus losing height to a dangerous extent It was probably brought to an approximately horizontal attitude by the use of the maximum possible up-elevator by the end of this dive Second, in spite of using all the devices provided, the commander found that he was unable to get her nose up and regain his lost height, the ship continuing horizontal flight probably for a few seconds Third, another

* Cmd 3825 (London H M Stationery Office) 2s 6d net.

dive at about fifteen degrees, during which she struck the ground In this last phase it was evident that those in charge had realised that a landing was inevitable and were seeking to minimise the crash Their efforts were so far successful that the actual mechanical damage was remarkably slight, and the estimated forward speed at the time of impact was no more than four to five miles per hour The fire broke out after the ship struck the ground, and but for this it is not improbable that there would have been no fatalities It is also definitely established that the loss of control during these phases was not due to any failure of the structure of the airship, or of the control gear

The primary cause of the accident was heaviness, which could only have been due to abnormal loss of gas This loss was twofold First, the bags had already given trouble by holing, due to rubbing against protruding points on the framework This was due to the wiring round the bags, by which the framework of the ship is slung to them parachute fashion, having been let out in order to accommodate larger bags and give extra lift This had been dealt with by padding the fouling points, but the Report makes it clear that the inspectors were by no means happy about it Secondly, there was probably a complete deflation of one of the larger forward bags, due to the "buffeting that it would receive in consequence of a tear in the outer cover" Exactly how much either one of these is contributory to the other is not suggested in the Report There might also have been an additional loss of gas through the gas valves, which were of novel design, if the ship had rolled excessively--and there had been expressions of opinion that *R101* was prone to rolling in rough weather

If this theory is accepted, it fully accounts for the unmanageability of the ship, and the suggestion that the height coxswain, only on duty a few minutes, had not had time to get the 'feel' of the elevators, while it is probably true, seems to have little to do with the real cause of the disaster In this connexion, it appears that the ship was always sluggish on horizontal control, as it came out of a dive much lower than was intended at the Hendon Air Pageant This was before the ship was lengthened, so that afterwards it was probably even worse, and the man in charge must certainly have known this

The other part of the Report, dealing with the responsibility for taking decisions as to making certain flights, has no direct scientific interest, but indirectly it provides damning evidence of the danger of the system of control of expenditure upon experimental work that is based upon the principle that work cannot "be proceeded with until the existing outlay is seen to be justified by results", o that such work must be held to an estimated time or expenditure The Report makes it only too clear that the decision to undertake the flight to India, and by inference *R100*'s Canadian flight as well, at a time when it was politically expedient, was very largely influenced by the necessity to rehabilitate the airship policy when it was becoming somewhat discredited owing to its continued failure to give spectacular performances

The Report is now public property, and as it has already been stated in Parliament that the decision upon the continuance of airship development was awaiting this, it would appear to be reasonable to examine the present position We have now the sister ship *R100* laid up at Cardington Two ships were purposely built in order that "accidental failure of one ship should not terminate the whole programme" The Report makes it clear, in fact it emphasises, that there was nothing fundamentally wrong with *R101*, either in general principles or structural design Logically, therefore, the experiment should proceed. We ought to be able to avoid a repetition of this catastrophe by taking precautions suggested by the various decisions in the Report Most of these are only too obvious now

A non-inflammable gas must be used This is a pity, as there was a distinct promise of success for a scheme for burning hydrogen in conjunction with the atomised oil in the engine This was a considerable economy, as it would derive power from the gas which has now to be deliberately thrown away as the ship becomes lighter, as fuel is consumed It is, however, inevitable, as the accident to *R101* would have been nothing like as serious had it not been followed by the instantaneous ignition of the gaseous mixture around the torn bag

Spectacular long distance flights must never be undertaken for psychological reasons alone The necessity for completing an advertised programme imposes upon the experimenter an extra anxiety that is quite unfair It is legitimate to suspect that the "very alarming experience when over the St Lawrence River" with *R100* nearly resulted in a similar tragedy The chafing of the gas bags and their consequent excessive leaking and weakening was the result of reducing the clearances between them and the frames to an amount that

was less than the designers originally thought safe This was only necessary in order that the long flight to India might be undertaken The introduction of the extra length must have made some difference in the handling of the controls, which could only have been mastered by the several watches of helmsmen after a long series of flights in all kinds of weather, under the easier conditions of mental strain that would prevail on an ordinary practice flight, in daylight, over familiar country, and without distinguished passengers on board

The question of the time taken to swing the controlling surfaces over by hand appears to need very full investigation The servo-assisted controls were removed in order to save weight, only after what would certainly have been full consideration of all the circumstances It should be possible to deal with this problem by some system of gyroscopic control which would anticipate movements of the ship's bulk from the normal, rather than wait for these to be read by a helmsman and then corrected, even with mechanical assistance

All ballast should be capable of being jettisoned immediately by the person in charge in the control room Such decisions have to be made and acted upon instantaneously If it is of any value to release the contents of a certain tank, that value is largely nullified if the commander has to come to the decision some minutes beforehand, in order to dispatch a man to perform the operation

The technique of emergency landing on the ground or water should be developed as part of the routine handling There does not appear to have been any concerted action of this kind in this case The handling of the ship in the last dip was obviously correct, and established the competence of those in charge at the time beyond all question, and but for the failure to release the front ballast in time, she would probably have gently stranded in a horizontal attitude It is significant, however, that both Disley and Church, who were called upon to perform the vital operations of cutting off the electric current and releasing the emergency ballast respectively, were off duty at the time, and would probably not have been so luckily available had the accident not have happened immediately after the changing of the watch That it is possible to land a large airship on the ground under normal conditions, as would prevail when doing such manœuvres for practice, has been proved by the *Graf Zeppelin* upon many occasions

The broader question as to the advisability of continuing airship development at all, also must be considered Here we cannot lose sight of the fact that there are two distinct outlooks, the war and the commercial uses It is certain that for patrolling the high seas the airship is quicker, cheaper, and has a wider range of vision than any surface vessel Its flying range is also greater than any heavier-than air craft Its relative unwieldiness, and consequent vulnerability to attack, must be put on the opposite side of the scale in judging its usefulness, but the exact balance between these cannot be judged by the layman It is certain that the distinctly naval type of airship development was only given up for reasons of economy, and the continued interest of the fighting services in them is proved by the fact that experiments upon releasing and picking up of fighting aeroplanes from airships have been carried out quite recently

Commercially, it is certain that their large size gives them an advantage over heavier than-air craft from the point of view of passengers' comfort, both for steadiness and room to move about The relatively small aeroplane will always be at a disadvantage in this respect, as even if worked in relays, the passengers' physical endurance will place a definite limitation upon the length of journey that they can undertake On the other hand, it is equally certain that until experience has proved that such a holocaust as the loss of *R101* is no longer to be feared, insurance rates alone would make the use of airships commercially impossible

There is a school of thought that now feels that we have contributed our quota to airship development for the present, and as larger airships are being built in the United States, and projected in Germany, we might stand aside and watch those for a period There are points in favour of this outlook, in that it is impossible to hide general results that are attained, even if it is desired to do so, a state of affairs that there is happily no reason to anticipate at the present On the other hand, there is that somewhat intangible confidence that comes with actual experience in design, building, or handling, that no interchange of written matter can ever give to a personnel It has been announced that a Government statement on policy with regard to airship development in Great Britain is imminent The points we have raised should be given due weight with considerations of economy, unemployment, and other more widely appreciated aspects of the problem

Constructive Excavation

The Palace of Minos a Comparative Account of the Successive Stages of the Early Cretan Civilization as illustrated by the Discoveries at Knossos By Sir Arthur Evans Vol 3 *The Great Transitional Age in the Northern and Eastern Sections of the Palace the most Brilliant Records of Minoan Art and the Evidences of an Advanced Religion* Pp xxiv + 525 + 24 plates (London Macmillan and Co , Ltd , 1930) 105s net

SIR ARTHUR EVANS began to excavate at Knossos in the winter of 1899–1900, and his annual campaigns have been almost without intermission, except during the War The first volume of this account of the results appeared in 1921, the second in 1928 , and there is still to be a fourth, and the much-needed index besides Even this, however, apparently, will only bring the story of the Palace down to the moment of its destruction What happened after that "final catastrophe" is nevertheless part of the history of the site, and an important phase in the transition from Minoan to classical Greek civilisation and it is to be hoped that, in some way or other, the very large mass of evidence which the site affords may eventually be made available, however inferior in artistic performance the later occupants may have been

The account of the successive systems of Minoan writing, to which occasional allusion is made here, is likewise reserved for the second and third volumes of "Scripta Minoa", of which the first was published in 1909

Following the convenient general programme, adopted in vol 2, of an orderly progress through the Palace buildings, the present instalment leads us first (§§ 68 74) through the "North west Insula", north of the central court and west of the seaward entrance , next (§§ 75-7) to the "North Entrance" itself, with its flanking porticoes and fragmentary reliefs of bull-hunting scenes , and then southwards along the east side of the central court, past the "East Postern" (§§ 78-9), and "Corridor, Portico, and Stairs" (§ 80), into the "Domestic Quarter" (§§ 81-2) with its "Hall of the Double Axes" (§ 83), "Queen's Megaron" (§ 84) and "East Treasury" (§§ 85-7) finally (§§ 88-9) the construction and relief-fresco decoration of the "Great Hall" take us above the "Domestic Quarter" back to the level of the Central Court For the whole of this eastern wing of the Palace lay deeply plunged in the steep eastern slope of the neolithic 'tell' on and around which the later structures were accumulated a protected position which accounts in great measure for the remarkable state of preservation in which the lower floors were found Of the "Great Hall", indeed, only a few blocks can be identified , but this stood on top of no less than four stories of corridors and chambers, connected by staircases, ventilated and fairly well illuminated by light-wells, and supplied by gravity with water from cisterns or conduits somewhere up aloft

It is necessary to insist on this elaboration of structure to appreciate the extent to which excavation has had to be supplemented here by thorough and durable reconstruction Minoan builders made much use of timber framing as well as of posts, lintels, jambs, and floor joists When the Palace was wrecked, these lasted long enough to allow rainwash and debris to fill completely the lower rooms and a good part of the first floor But in time decay set in , floor slabs settled down on the filling below them , but lintels and timber-courses left cavities and disintegrated walling, which only remained erect because it could not fall sideways The risks, as well as the problems, of excavation must have been serious , and it was only when the same Cretan climate began to attack modern substitutes, that timber gave place to iron girders, and iron in turn to ferro-concrete (p 288), strong enough, as the event showed, to resist even so severe an earthquake as that of 1926 Through this chapter of accidents, Knossos opens a new period of the scientific exploration of antiquity, and Minoan civilisation becomes appreciable as an organic whole, as Græco Roman life is revealed in the *nuovi scavi* at Pompeii

These architectural discoveries are, however, only the plot or framework of the narrative Borrowing a literary technique, rather from saga than from the modern novel—for the topics and episodes outnumber those of the "Old Wives' Tale"—Sir Arthur Evans has succeeded with remarkable ingenuity in communicating, as he leads us round his Palace, the kind of incidental commentary on the contents, as well as the framework, which a Minoan occupant and connoisseur might have given to a guest from contemporary Mycenæ Room by room, something strikes the attention—as it struck the spade—and halts the party In the "Corner Sanctuary" (§ 69) it is the spiral fresco on the ceiling and the lifelike miniature painting on the walls, earlier, of course, than the furniture, which has been accumulated gradually since the room was last decorated and this leads on to dance-scenes and occasions for dancing, through the ages, to the *pentozális* and *sigandós* which they are going to dance in Cretan villages in the twentieth century—and

with much the same song accompaniment, for all its Venetian name, and so on to siege scenes and the silver cup from Mycenæ, to comparison between fresco painting and the 'metal painting' of the 'lion-dagger', and the Homeric 'Shield of Achilles', to religious scenes and the 'Ring of Nestor'

Through all this, one recurrent thought leads on to the supreme instance of such dependence of Minoan *bijouterie* and *klein kunst* on inspiration from the Palace frescoes and reliefs, namely, the bull hunting scenes of the North Entrance, all but vanished, yet perpetuated in the 'Vaphio cups' (§ 75) and the British Museum's fragments from the Treasury of Atreus (§ 76), and we come to know what is lost, the more vividly, through discussion (§ 77) of the technique of the Minoan 'taureador', so far beyond that of modern 'rodeo' experts, yet surely vouched for by the consentient evidence of scores of episodes, on gems and other works of popular art There is still a good deal to be made out about the details Figs 150 and 158, for example, tell more than even Sir Arthur has seen

Similarly, the wonderful ivory figures from the "East Treasury" (§§ 86-7) lead to reconstruction of what must have been a superb Minoan plaything—if indeed it was not of more solemn use—and to the identification of the "Boston Goddess" and her 'migrated' Boy God, as central pieces from this composition Without necessarily accepting all that is suggested about the "older matriarchal stage of social development", we have here, at a very high power, religious beliefs and feelings about the order of Nature and its meaning for social beings, and remarkable anticipations of elements and incidents in Christian legend, to which, as might almost have been foretold, the mysterious gold rings of Thisbé are principal contributors To the history of these rings, Sir Arthur has a little more to add (p 471), and a notable corroboration of one of the queerest of the topics on them He has also valuable confirmation (p 420) of the authenticity of the "Fitzwilliam Lady", if her actual bully-beef complexion was meant to be powdered and rouged Will Sir Arthur essay reconstruction here too ?

It is only because such a volume as this is not likely to be reprinted that a few slips of the pen are noted in conclusion On p 258 (l 6 from bottom) 'later" should be "earlier", on p 289, n [2], N W " seems required by the context, on p 183 l, "1906" should be "1896" p 323, "convex" fluting should be "concave", p 386, the monolith bathroom is at Tiryns, not Mycenæ, p 391, "Margaret" should be "Harriet", p 439, l 40, "of" should be "by", p 525, l 23, "about" should be "above" and Fig 307 is more nearly double than treble scale JOHN L MYRES

Geological Survey of the Scottish Coalfields

Geological Survey, Scotland The Economic Geology of the Ayrshire Coalfields Area 3 *Ayr, Prestwick, Mauchline, Cumnock, and Muirkirk* By V A Eyles J B Simpson, and A C MacGregor Pp viii + 175 + 3 plates (Edinburgh and London H M Stationery Office, 1930) 4s net

THE Geological Survey of Scotland is continuing the excellent work which it has commenced in issuing memoirs describing in detail the geology of the districts of economic importance, more particularly of the various coalfields Whatever faults may be found with this work of the Survey, it cannot be accused of undue haste, for the immediate precursors of the present volume were published so far back as 1925 The present memoir is the third of the series which has been issued under the general title "Economic Geology of the Ayrshire Coalfields" The first two of these dealt with north Ayrshire, whilst the present volume deals with the northerly portion of central Ayrshire

The work is very complete, the first chapter is a general one dealing with the general geological succession of the area and giving a sketch of the geology of the district It is shown that although important coal seams occur in the Carboniferous Limestone, more especially in the central group of the three into which this series is divisible, the most important division from the economic point of view consists of the Coal Measures These are divided into two groups, the so called barren red measures and the productive measures, which overlie the former group In these red measures, coal is practically absent, except for a few thin seams towards the base of the group Its dark beds, frequently dark red or purple as their name implies, form a very distinct contrast to the grey, or at any rate light coloured, beds of the productive coal measures The New Red Sandstone overlying the barren red measures is briefly described, as also are various intrusive igneous rocks, whilst the superficial recent deposits are briefly referred to It may be noted that this preliminary chapter closes with a few historical notes of very decided interest in the economic history of Great Britain

The next chapter describes the Pre Carboniferous

rocks, namely, the Silurian and Old Red Sandstone, and the following chapter is devoted to the Calciferous Sandstone, which here forms the lower part of the Carboniferous series. The next four chapters describe in detail the Carboniferous Limestone series in different portions of the area discussed, describing in detail the Lower and Upper Limestone group and more particularly the Limestone Coal group in each section. The presence of ironstone is more than once referred to, but it is, unfortunately, only too evident from the descriptions given that the ironstone of this portion of the coalfield is practically worked out. The next chapter describes the Millstone Grit in quite sufficient detail, and the next five chapters are devoted again to a description of the Coal Measures in various sections of the area here discussed, special care being taken to describe the igneous intrusions in each case.

The following chapter deals with a very interesting subject, namely, the Permian rocks of the Mauchline Basin and the coalfield concealed under these rocks. The authors conclude that there is no doubt that a very large field of unworked coal exists within the coal measures concealed beneath the Permian rocks, and that it is very probable that three important seams occur in workable thickness throughout the greater part of this concealed coalfield. It is shown that all the seams are likely to be thickest in the south-east, where they lie at distinctly greater depths than at the other end of the coalfield. The authors consider the possibility of some of the coal being more or less burnt by igneous rocks, but hold that the chances of their being thus burnt are considerably less on the east and north sides than on the western side, and they therefore conclude that it will probably be more profitable to open this concealed coalfield from the south-east rather than from the north-west.

There is a very short chapter dealing with superficial deposits, which are here of very little importance, whilst a final chapter is devoted to other minerals of economic importance, namely, building stones, road stones, etc., clays of various kinds, barytes, ores of lead, iron, copper, and antimony, and graphite, whilst finally a few words are devoted to what has been described as a deposit of china clay. It can only be said that this last section rivals the famous chapter on "Snakes in Ireland". In an appendix there is a short glossary of the mining and technical terms used in this memoir, which will no doubt be found useful. It may, however, be suggested that a comprehensive glossary dealing with the whole series of the Ayrshire coalfields, or even with the whole of the Scottish coalfields, might be preferable, would save a large amount of needless repetition, and would probably be more generally useful.

Like the rest of the series, this volume is well prepared and illustrated by a number of plates and figures. The work was undoubtedly worth waiting for, but it is difficult to see why the period of waiting should have been so protracted.

Blast Furnace Practice

Blast Furnace Practice. By Fred Clements. Vol. 2: *Design of Plant and Equipment.* Pp. 509. Vol. 3: *Operation and Products.* Pp. 400. (London: Ernest Benn, Ltd., 1929.) 63s. net each vol.

WITH the publication of these two massive volumes, Mr. Clements has completed the task which he set himself, of presenting a complete account of modern blast furnace practice based on a comparison between the principal plants in Great Britain and abroad. The amount of labour involved has been very great, and all metallurgists must be grateful for the mass of data thus made available, and for the pains taken by the author to present them in the form of tables and diagrams. The folding tables contained in pockets at the end of each volume in themselves represent an enormous labour, and provide a comprehensive survey of existing practice. Such surveys are naturally soon out of date, as furnaces are continually being rebuilt, and some alteration of practice is sure to occur. On the whole, however, blast furnace practice remains, except for minor details, comparatively unchanged over long periods, although practice in different countries varies widely. Moreover, in spite of the frequent announcements of the success of various direct methods which are to supersede the blast furnace, there is no immediate indication of iron or steel being made from the ore in any substantial quantity without passing through this apparently crude but nevertheless efficient apparatus. This work, therefore, the most complete yet attempted on the subject, is likely to be useful for years to come.

The second volume is concerned with the actual construction of the furnace, the character of the lining, the appliances for charging and for handling the iron and slag, and also with the subject of the blast and the stoves and blowing engines. The drying of the blast, by means of silica gel, which one might expect to find here, was actually described in the first volume. There is, indeed, a certain arbitrariness in the arrangement

of the matter, and as each volume has a separate index, it occasionally needs a little trouble to find information on a point which does not have a chapter to itself The third volume, for example, opens with chapters on the calculation of the burden and on the control of temperatures, followed by others on operating problems, but chapters on economics and on such minor subjects as the provision of ambulances and welfare work are interposed between these and the later accounts of the cleaning of blast furnace gas and the utilisation of by-products Within the limits of each chapter, however, the arrangement of the matter is usually logical, and the expression is clear throughout, the writing being pleasantly free from the jargon too commonly found in books on a highly technical subject The admirably clear diagrams, again, are a feature which cannot be too highly commended

As was remarked in the review of the first volume, the weakest part of the work is its treatment of the chemical reactions in the furnace This defect is also seen in the last volume, in the account of the use of slag for the manufacture of cement, where it would have been interesting to see references to modern work on the nature of cements, on which a very extensive literature exists The utilisation of slag is a subject of great importance Where the texture of the slag is such as to make it suitable for use in tar macadam roads the problem has been solved, but not all blast furnace slags have such a texture, and the manufacture of cement provides a possible outlet, the high qualities of a properly made blast furnace Portland cement having been amply demonstrated

Chemists should find much to interest them in a study of the blast furnace, in which a number of balanced reactions of a complex kind proceed continuously on an enormous scale The work of Bunsen, Playfair and Lowthian Bell placed that study on a scientific basis, but it has been strangely neglected since, although many laboratory studies of the simpler reactions between the oxides of iron and those of carbon have been undertaken The recent work of Bone has shown how remarkable are some of the reactions, and how fully they deserve the attention of chemists The elaborate treatise of Clements will furnish them with ample information as to the conditions under which those reactions proceed on the large scale, and much that is suggestive should be found in its pages The practical metallurgist, on the other hand, will value a work which, if showing some minor defects, has the great merits of clear presentation and remarkable thoroughness

Our Bookshelf

Photographisches Praktikum für Mediziner und Naturwissenschaftler Herausgegeben von Dr Alfred Hay Pp x + 531 + 3 Tafeln (Wien Julius Springer, 1930) 39 gold marks

THIS handbook is the work of sixteen contributors, each dealing with some application of photography in medical and semi medical work The range covered is very considerable and dealt with in great detail The illustrations are very well reproduced, as might be expected in such a book, but do not occupy an undue proportion of the space It is sometimes urged against photographic recording that the final result often exaggerates unwanted detail and suppresses the points required It is true that the camera and plate are not capable of selecting intelligently what the observer wants, but a study of this volume shows that a great deal can be done to attain this end

Besides chapters devoted to record work pure and simple, such subjects as the electrocardiograph, the photographic recording of muscle movements, and the photographic side of X ray work are dealt with

The work is concerned primarily with medicine and the related sciences and indeed it is rather difficult to justify the ' Naturwissenschaftler " of the title This is apparently the reason for there being no mention of the photographic plate as a measuring instrument The technique of photographic photometry is very complex as so many precautions are essential before the density of the image can be relied on as a measure of the intensity of the incident radiation

The volume is essentially a practical handbook for use as reference, but the two first chapters are devoted to the optical basis of the camera and the physical and chemical properties of the light sensitive material respectively The latter is written from a practical point of view, and is little more than a series of directions No attempt is made to explain the reactions of silver bromide which have been discovered in recent research This is to be regretted, as much of this work throws considerable light on the questions of exposure, development, etc Photography has developed so long on purely empirical lines that it is still not realised that there is a substantial basis of theoretical knowledge which can be of value in most practical applications

A Practical Treatise on Single and Multi Stage Centrifugal Pumps By Raymond Defeld Translated by C W Olliver Pp x + 221 + 42 plates (London Chapman and Hall, Ltd , 1930) 21*s* net

To the British manufacturer of centrifugal pumps, as well as to the student who is specialising in the subject, the appearance of the translation of a volume written by a leading technical official of a well-known Continental firm can scarcely fail to be of interest, if only for the opportunity it should afford of comparing British and foreign practice in various points of detail and design The author is chief engineer of the Ateliers de Constructions

Électriques de Charleroi, more commonly known as the A C E C, and he is also professor of hydraulics at the University of Charleroi two outstanding qualifications which should admirably equip him for the preparation of a manual of sound practical value

The translator's preface claims that Prof Defeld has made a life study of the problems connected with centrifugal pumps So much, indeed, may be readily conceded, and the volume is welcome as the contribution of an acknowledged expert It is received as a standard work in Belgian universities At the same time, without being unduly captious, perhaps we may be permitted to suggest that, as a treatise, the treatment is somewhat uneven and the style concise to the point of abruptness The book, in fact, may not inaptly be described as a specialised note book, better suited for reference purposes to the expert and advanced student than for guidance to the beginner, despite the fact that the leading principles of the subject are demonstrated, though somewhat summarily, in the early chapters As might be expected (though the feature has obvious drawbacks), the illustrations, which are very profuse and not free from redundancy, are chiefly drawn from the products and installations of the A C E C The translator has provided what seems to be a very satisfactory rendering, and the publishers have produced an attractive volume

B C

Grundlagen der Analysis (das Rechnen mit ganzen, rationalen, irrationalen, komplexen Zahlen) Ergänzung zu den Lehrbüchern der Differential und Integralrechnung Von Prof Edmund Landau Pp xiv + 134 (Leipzig Akademische Verlagsgesellschaft m b H, 1930) 9 80 gold marks

Many books on analysis have an introductory chapter on the elementary theory of number, but it is rarely sufficiently detailed to provide a complete logical account based on a few clearly stated axioms The present work by the eminent professor of mathematics at the University of Göttingen occupies a unique position in so far as it aims at giving a rigorous and complete deduction of the properties of numbers, up to and including complex numbers, from the five axioms of Peano, and that, too, by elementary methods, such as a student should be able to understand at an early stage of his university course

There are five chapters, dealing in succession with natural numbers, fractions, sections (*Schnitte*), real numbers, and complex numbers Each chapter gives, in strictly logical order, the definitions and propositions requisite for the proofs of the theorems concerning the application of the fundamental arithmetical operations of ordering, addition, and multiplication to the numbers with which it is concerned The last chapter, in addition, gives the definitions and theorems relating to subtraction and division and to sums, products, and powers of complex numbers The book undoubtedly fills a gap in the list of mathematical books, and should prove exceedingly useful to every reader who feels the need of a clear and rigorous foundation for mathematical analysis

Systematic Crystallography an Essay on Crystal Description, Classification and Identification By T V Barker Pp xi + 115 (London Thomas Murby and Co, 1930) 7*s* 6*d* net

It is clearly desirable, whether one looks forward to the use of goniometric methods as an everyday means of identification or not, that a research worker in one laboratory should issue the results of his study in exactly the same form as an independent worker in another But in the anorthic system, the odds against an identical treatment, even in relatively simple cases, are at least fifty to one Yet it requires only a little care in the choice of the simplest possible indices, aided by a few rules and conventions no more unreasonable or difficult to remember than the convention that the axial angle β of a monoclinic crystal is the obtuse angle, and the odds may be reversed The necessary rules, and the method of their application, Dr Barker has set forth clearly Once given the uniformity of description which would be consequent on a universal adoption of this system, the preparation of determinative tables of crystals, classified by their angles and symmetry, is relatively simple, and a specimen of such a table is given, covering some hundred substances That such tables are of practical value is shown by Dr Barker's successful identification of nine substances chosen from this hundred, by their aid alone It is perhaps not too much to suggest that it is the duty of every crystallographer to study and adopt the proposed conventions—or to put forward better ones instead

Air Ministry Meteorological Office British Rainfall 1929 the Sixty ninth Annual Volume of the British Rainfall Organization Report on the Distribution of Rain in Space and Time over the British Isles during the Year 1929, as recorded by over 5000 Observers in Great Britain and Ireland (M O 325) Issued by the Authority of the Meteorological Committee Pp xix + 298 + 4 plates (London H M Stationery Office, 1930) 15*s* net

This volume, the sixty ninth of a valuable series, gives a full account of the rainfall of the year 1929 on the basis of records from 5180 stations It includes maps, tables, and descriptive matter showing the distribution of rainfall each month and for the whole year and its relation to the average, together with studies of heavy falls of rain on particular days, of the number of days with rain, and of well marked spells of wet and dry weather during the year There are also records of evaporation and of percolation through the soil

The period from January to September was drier than any similar period in the last sixty years, but that from October to December was the wettest on record for the period In fact, an enormous quantity of rain fell during this period in the south-west of England and South Wales

A short article at the end of the volume deals with the rainfall of Pembrokeshire, and there is another special article on the shielding of rain gauges.

Magnetic Hysteresis on Weber's Theory

IN his recent valuable review of the development of the subject of magnetism in discontinuous media [1] Prof. McKeehan makes the statement that the theory, as given in the papers to which he is there referring, "makes no provision for that magnetic hysteresis which is the distinguishing feature of ferromagnetism." This statement is literally quite correct in so far as there was no attempt made in these papers to deal with the subject of hysteresis. But it would be misleading if it were taken to imply that Weber's theory cannot give an account of the phenomena of hysteresis. The existence of directions of equilibrium for magnetisation, alternately stable and unstable, under the Weberian internal field, compel phenomena of that type.

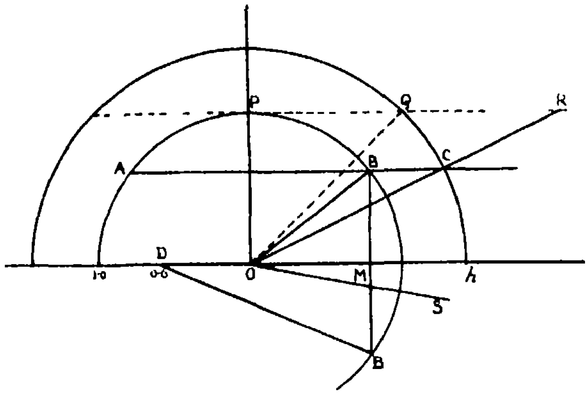

FIG. 1.

A complete discussion, even for the most important case of cubic crystals only, though of great interest, would be unsuited to the columns of NATURE, yet sufficient evidence as to the general validity of the theory may be afforded by the accompanying diagrams, which refer to magnetisation parallel to a face plane of a cubic crystal.

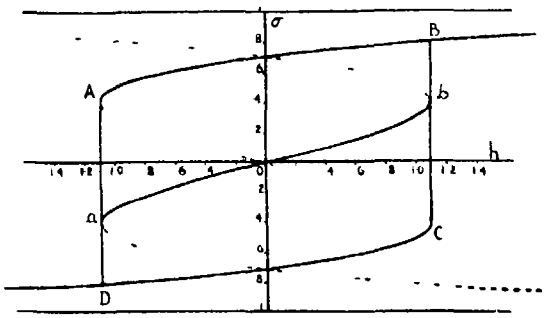

FIG. 2.

Fig. 1 shows a simple geometrical construction which is applicable to this case. The two circles have radii 1 and h respectively, where h is the magnitude of the external field expressed in terms of the maximum value, taken as the unit of field strength, of that component of the internal field which is transverse to the direction of magnetisation. The lines PQR, ABC, and Oh are all drawn in the direction of magnetisation, and OS is in the direction of a crystalline axis of stable magnetisation. If $hOS = \theta$, and $OBA = 4\theta$, while OC is in the direction of the external field, with $COS = \theta_0$, the construction gives $OCA = \theta_0 - \theta$, and corresponds to stable magnetisation. DB' represents the internal field, the component MB' of which is

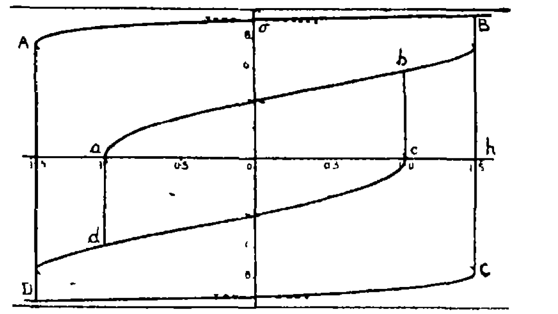

FIG. 3.

balanced by the component MB of the external field. OM gives the fractional magnetisation, σ, in the direction of the external field. If h be increased so that OC becomes OR, we have $\theta = \pi/8$, and instability is just reached.

In Fig. 2 the curve of magnetisation $BAOCD$ is shown for the cases $\theta_0 = 0$ and $\theta_0 = \pi/4$, the equation being

$$h = 4\sigma(1 - 2\sigma^2).$$

The curve for the reverse field is also shown. Unstable stretches are dotted and the hysteresis loop is $ABCD$. So long as h remains less than 1·1, hysteresis does not appear.

In Fig. 3 similar data are exhibited under the condition $\theta_0 = \pi/8$, the equation being

$$h = \frac{1 - 8\sigma^2(1 - \sigma^2)}{\sqrt{1 - \sigma^2}}.$$

So long as $h < 1$ no hysteresis appears. If $h > 1 < 1{\cdot}466$ approximately, the hysteresis loop is *bacd*, and the magnetisation oscillates in direction between the two mutually perpendicular axes $\theta = 0$, $\theta = \pi/2$. If h exceeds the preceding upper limit, the hysteresis loop $BADC$ is described, and the direction of magnetisation oscillates between $\theta = 0$ and $\theta = \pi$.

These results apply under the presumptions that there are no thermal motions, and that the atomic magnets can be regarded as ideal.

Absorption Spectra of Saturated Chlorides of Multivalent Elements

FRANCK and his co-workers have shown that the vapours of alkali halides show a continuous absorption spectrum beginning from a long wave-length limit and extending towards the ultra-violet. He interpreted the absorption spectrum as follows: if we take a substance like sodium chloride the valency electron of Na in the normal state may be supposed to pass over completely to Cl and the combination consists of Na^+Cl^-. Such a combination is called ionic. When light falls on sodium chloride vapour, the electron passes over from Cl^- to Na^+, the molecule thus splitting

into Na and Cl Franck obtains the heat of formation Q of NaCl from atomic Na and atomic Cl with the aid of a Born cycle and finds that $Q = Nh\nu$ where ν = frequency of the beginning of continuous absorption

The absorption spectra of saturated halides of multivalent elements have been studied in this laboratory for some time past, and yield results of general interest The chlorides of tetravalent elements, CCl_4, $SiCl_4$, $TiCl_4$, and $SnCl_4$, are the easiest to investigate, because they are usually fluid, and vapour can be obtained with the greatest ease We found generally that these chlorides, like sodium chloride, give a continuous absorption beginning from a long wave-length limit and extending towards the ultra violet

At first the frequency of the beginning of absorption seemed to have no connexion with the heat of formation in the process $M + 4Cl = MCl_4 + Q$, but it turned out ultimately that $Nh\nu = Q/4$ Thus to take a definite example, in $SnCl_4$ the value of Q in the process $Sn + 4Cl = SnCl_4 + Q$ is found to be 306 gm cal, while the absorption spectrum begins from λ = c 3860, corresponding to 74 gm cal, which is about $\frac{1}{4}$ (306) In CCl_4 absorption begins at c λ = 2400 corresponding to 118 gm cal, while Q is nearly four times as large, namely 464 gm cal, provided the heat of vaporisation is taken to be 282 gm cal as proposed by Fajans

The explanation is quite simple The four chlorine atoms may be supposed to be symmetrically distributed about carbon or tin and the whole energy of formation is equally shared by the four chlorine atoms The effect of light is to remove the electron from one Cl ion to the carbon shell, thus splitting CCl_4 into CCl_3 and Cl

The relation may be expected to be generally true The vapour of the saturated halide of an n-valent atom is expected to show beginning of continuous absorption at $\nu = Q/nh$ where Q is the heat of formation in the process $(M) + n(Cl) = (MCl_n) + Q$ It can be shown from considerations of a Born cycle that

$$Q = \lambda_M + \frac{n}{2}D_{Cl_2} + R - \lambda_{MCl_n},$$

so that
$$\frac{Q}{n} = \frac{1}{2}D_{Cl} + \frac{R}{n} + \frac{\lambda_M}{n} - \frac{\lambda_{MCl_n}}{n}$$

where
$$[M] + \frac{n}{2}(Cl_2) = [MCl_n] + R$$

D_{Cl} = *heat of decomposition of* Cl, and λ_M, λ_{MCl_n} are the heats of sublimation of the element and the chloride respectively These are very often not known But Messrs Deb and Mahanti in this laboratory have extended the investigation to the magnesium and aluminium halides (divalent and trivalent) and have found good agreement with theoretically predicted values provided the assumed values of λ_{MgCl_2} etc, which are yet unknown, prove to be correct But no agreement has been found in the case of $HgCl_2$, which seems to behave like HCl or AgCl, which according to Franck, do not conform to the type called ionic binding, but to atom binding

Raman Spectra of Crystals

I HAVE been investigating the Raman effect in a number of crystals, using the same method of excitation which proved to be particularly successful with gases [1] The primary source consists of a powerful water-cooled mercury arc which gives an extremely intense and sharp resonance line λ2537 The advantages of this method are (1) the ratio of the intensity of the line λ2537 to the other mercury lines in the ultra-violet is so large that in a spectrogram of moderate exposure all the Raman lines are excited by the former radiation (2) a short exposure is required (10 minutes to three hours), (3) a wide range of frequency shifts is available (about 20 000 cm^{-1}), (4) the exciting radiation can be easily absorbed by a filter of mercury vapour between the substance and the photographic plate, thus allowing the observation of modified frequencies in the immediate neighbourhood of the primary line

In the Raman spectra obtained by this method, many new faint lines are observed in almost any crystal which has been tried and the intense lines can probably be measured with more accuracy than has hitherto been done, on account of the large dispersion which it is possible to use But here I will report only the most interesting new features which have been brought out

I have succeeded in recording the Raman spectra of fluorite and rock salt, which, so far as I know had not been observed before Fluorite gives a Raman shift of 321 5 ± 1 cm^{-1}, corresponding to an infra-red wave-length of 31 1 μ, which is in good agreement with the wave-length of the residual rays, 31 6 μ, and besides this, a group of lines of very large frequency shift, which will be considered later

The Raman spectrum of rock salt is very weak (an eight hours' exposure was required using a crystal 5 cm thick) and shows a very peculiar structure It consists of a continuous band with fairly sharp limits, extending from about 165 cm^{-1} to 365 cm^{-1} Within this band, a rather sharp line appears at 235 cm^{-1} Rock salt, owing to the simple structure of its lattice, possesses only one infra-red reflection maximum at 52 5 μ This does not coincide at all with the frequency of the Raman line

A still more peculiar phenomenon is exhibited by calcite and fluorite These crystals show, besides the ordinary Raman lines a group of lines with a very large frequency shift, much larger indeed than any which has been observed so far in the Raman effect The following table gives the numerical values of $\Delta\nu$ in cm^{-1} (± 2 cm^{-1})

Calcite	Fluorite
7270 3	7255 8
7345 2	7273 3
7395 0	7285 4
7455 5	7297 6

That these Raman lines are really excited by the line λ2537 and not by other lines of longer wave-length, is shown by the fact that they disappear on introducing between the source and the crystal a screen which absorbs the spectrum beyond λ2700 and transmits the strong Raman lines $\lambda\lambda$2967, 3022, 3125 31 Besides this their frequency differences from these mercury lines do not agree with any known Raman shifts

The new lines are weak as compared with the strong Raman lines of smaller frequency shift In the case of calcite, an exposure of about 30 minutes is required to bring them out while one minute is enough for the strongest line, $\Delta\nu$ 1086 cm^{-1}

I have not been able to find a reasonable explanation for these Raman lines It is very unlikely that they should correspond to vibration frequencies of the crystal since such high fundamental frequencies are never found in molecules or crystals, even when containing hydrogen atoms, and the occurrence of higher harmonics in Raman effect without the lower harmonics showing at all seems even more improbable I am rather inclined to attribute the new lines to

electronic transitions, although the existence of such levels in CaF_2 and $CaCO_3$ seems rather strange

I may add that analogous lines have been looked for unsuccessfully in ice, quartz rock salt, gypsum, anhydrite aragonite, and barite

Liquid Drops on the Same Liquid Surface

As a confirmation of L D Mahajan's view that water is a suitable liquid for the formation of liquid drops floating on its own surface[1] I can adduce two observations, the first of which is analogous to his observations at Den Kund

For several years I have had the opportunity of observing such floating drops of water in the Strait of Trogir (Trau), on the seaboard of Jugoslavia (Adriatic Sea) When the sea is quite calm, the drops dripping from the oar blades and falling on the surface of the sea, sometimes throw out, from their falling point, one or more such floating drops, which, after a quick motion last for several seconds Such drops sometimes spray from the acute crest of the first of the lateral waves which accompany a steamer in motion The temperature of the sea in such cases was probably 18 23 C

Such floating drops (primary) can be produced in abundance in the following way From a nozzle with a small circular orifice a fine jet of water issues with a moderate velocity and is falling on a surface of water The orifice should be kept at such a height

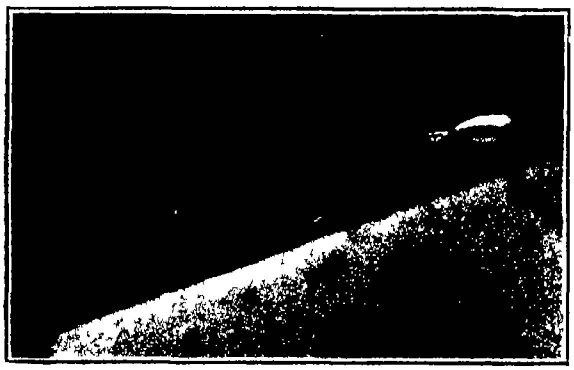

FIG 1 Velocity of efflux 86 6 cm sec, height of jet, 0 7 cm reduction 0 68

above the surface that the jet reaches it in its instability range which lies between the place where its vibrations originate and where it is resolved into drops Then from the point of incidence a great many floating drops are seen moving in different directions, forming a regular fan like pattern The velocities of efflux range from some 250 cm /sec to a few mm /sec In the last case only single drops leave the orifice and form on the surface—either directly or coalescing from two—uncommonly large drops (by estimation up to 6 mm) which last about 3 seconds In my experiments the diameter of the orifice was 0 5 mm , while the height of the falling jet was from 0 5 to 1 5 cm and they were performed at room temperature

The smaller the terminal angle of the jet or the greater the velocity of efflux the narrower is the fan of moving drops With fairly high velocities and rather small angles (about 45°) the fan grows narrower to some 20° 30° or gets reduced only to one ray of the drops In this case, the greater part of the falling jet reflects in the plane of incidence and forms a low parabola, consisting of dense drops, which, after a renewed fall on to the surface proceed in a straight direction In the case of vertical or nearly vertical incidences and of velocities smaller than 120 cm /sec the fan of the drops comprises 360°, and the drops spray fan like in all directions

The average diameter of a drop is 2 mm It is smaller if the velocity of efflux is greater It lasts, on the average, 2 seconds Single drops, especially

FIG 2 Velocity of efflux 89 1 cm sec height of the jet 1 1 cm , reduction 0 70

those which have returned from the wall of the vessel, lasted up to 5 seconds

The photographs reproduced herewith have been made from a nearly vertical position while the surface of water was obliquely lit by the sun or arc light They represent these drops in motion (time of exposure 0 04 sec) An arrow shows the incidence of light Each drop in motion showed above the dark base as a pencil of parallel lines, which corresponds to the optical images, as formed on the drop[2] Three parallel lines regularly correspond to one drop These are well seen on the drops which move more or less perpendicularly to the incident light On the side facing the source of light there appear two lines very near each other, while the third is somewhat farther away Their relative intensities are changeable Often, also the third line is double Bright lines near the point of incidence of the jet usually show a periodical granulation This can be ascribed partly to the vibrations of the drop, owing to which it periodically changes shape partly to the jumpy motion Such granulation is well shown on the under exposed photographs (Fig 2) That these are really drops, and not bubbles can be seen from the fact that they throw a *shadow on to the white part of* the bottom of the vessel

The above described phenomenon can be shown by experiment with both distilled and tap water Success depends on the freshness and cleanness of the surface of the water used Even the least traces of grease make success impossible The very touch of the *surface with the fingers* lessens the range and life of the drops

The drops are not reflected at the wall of the vessel itself, but return before coming to it Drops of small velocity return at a distance of nearly 1 cm from the wall of the vessel This distance decreases with increase in the velocity The drops seem to return owing to the motion along the slope of the surface, which slowly ends in the angle of contact

As to the origin of this phenomenon it should be kept in mind that the jet in its state of instability breaks up into drops on the vibrating surface at the

point of incidence Here the drops reflect in various azimuths, according to the momentary position of that part of the surface on to which they fall

University Entrance Scholarships for Science

I HAVE read with great interest the recent correspondence in the *Times* on science in scholarship examinations and the comments upon it in the leading article in NATURE of Mar 28 I should like to present a point of view rather different from any which have hitherto been put forward and to support it by a number of facts which, in my opinion, have not yet received the attention which they deserve I believe that the science specialist at school does devote a reasonable amount of time to literary subjects and does leave school with a satisfactory interest in literary culture, whereas the humanist devotes little or no time to the study of science and leaves school with an attitude of condescension towards it, which savours of intellectual snobbery and does little credit to the type of education which he has adopted

In support of this view, I propose to outline the typical preparatory and public school education of both an intending science scholar and a classical scholar The latter usually commences Greek at his preparatory school, so he begins some measure of specialisation at the age of about eleven He then spends the first two years of his public school career on a course of 'general education', which includes six periods a week of Greek and only three periods a week of science Having taken the School Certificate, he then commences specialisation in earnest and the time which he now devotes to science is reduced to one or two periods a week for the rest of his time at school, or perhaps only for the first year of specialisation I should add that, whereas the classic does only three periods a week of science in his course of general education, intending specialists in modern languages or history do some seven periods a week The future science scholar, on the other hand, arrives at his public school having done little or no science and spends his first two years on precisely the same course of work as the intending modern language or history specialist He is, quite rightly, not allowed to specialise at all until he has passed the School Certificate, and even then his course includes some eight periods a week of literary subjects The same thing is also true of the poorer boys, who appear to be the chief concern of the headmaster of Charterhouse, these boys will be at the day schools, and it is laid down in the Board of Education Regulations for Advanced Courses in Science that from one quarter to one third of the time must be devoted to literary subjects I think that the statistics which I have quoted are typical and they show quite clearly that it is the classical scholar who is the real culprit in this matter of premature and narrow specialisation

If we now turn to the attitude shown by the specialist to subjects other than his own after he has left school, I feel that the facts again point the finger of accusation at the humanist rather than the scientist In this respect I would venture to add my testimony to that of Prof A V Hill in defending the interest taken by the professional scientist in art and literature, while the interest of the mathematician in music is proverbial But the classic has little interest in, and perhaps even less knowledge of, scientific culture In fact, so narrow is his interest in even Greek culture, that when the Oxford University Press wish to publish a book on the "Legacy of Greece", they invite scientists such as Dr Singer to write those sections of the book dealing with the distinguished contributions of that civilisation to the various branches of science The headmaster of Charterhouse states in his letter that science is destined to play an ever increasing part in the affairs of the State, and in recent years leading articles in NATURE have deplored again and again the reactionary attitude of the Civil Service to scientific research and its introduction in State departments and the Services It is surely not without significance in this respect that the large majority of Civil servants have had a classical or humanist education

In conclusion, I venture to hope that no more will be heard of the dangers of premature specialisation in science, which, I think I have shown, are grossly exaggerated, but that attention will be turned to the far more urgent problem of ensuring that all specialists in the humanities shall devote at least four periods a week to science For, until this is done, I shall continue to maintain that it is they, and not the scientists, who are the real offenders in this matter of specialisation

Conditions of Silver Chromate in Gelatine Hydrolysed and Electrodialysed to Different Extents

IN a series of papers, Dhar, Chatterji and collaborators have shown that if a reaction between two salts giving rise to an insoluble product is allowed to take place in gels, the insoluble substance exists in colloidal condition in the gel and the formation of Liesegang rings is due to the coagulation of the colloid It has been shown, however, by Williams and Mackenzie[1] and Bolam[2] that the insoluble substance produced by the reaction between two salts exists in supersaturated condition in the gel, and their results support the theory of the formation of Liesegang rings proposed by Wi Ostwald[3] Experiments have been carried out by us to study the condition of silver chromate in gelatine hydrolysed (*by heating*) *and electrodialysed to different extents*, by determining the contact potential of pure silver in a mixture of $N/100$ silver nitrate, $N/100$ potassium chromate, and 3 per cent gelatine

So long as the mixture remains yellow and there is no visible precipitation of silver chromate the contact potential remains the same as that of silver in silver nitrate of the same concentration as in the mixture, but with the appearance of the precipitate, the contact potential gradually decreases and tends towards a limiting value The general conclusions from the measurements of contact potential can be summarised as follows

(1) More than 95 per cent of the silver chromate remains in the ionic condition in the gel (2) The power of gelatine to inhibit the growth of crystallisation centres decreases with the progress of hydrolysis (3) The inhibitive power of gelatine increases with the progress of electrodialysis (4) The inhibitive power of gelatine is closely associated with its pH, and the smaller the pH of gelatine the greater is its inhibitive power (5) The solubility of silver chromate in unhydrolysed gelatine is not increased by decreasing its pH (6) The solubility of silver chromate in gelatine increases with an increase in the degree of its hydrolysis

It is also found by varying the concentrations of the reactants (silver nitrate and potassium chromate) that the precipitation of silver chromate follows the usual

rules of solubility product On subjecting the mixture of silver nitrate and potassium chromate in gelatine to cataphoresis, silver chromate formed by the interaction is not found to carry any charge (either in the yellow mixture before the appearance of the precipitate or in the reddish turbid mixture after some precipitate has appeared) These results, therefore, show that most of the silver chromate in gelatine in these experiments is in ionic and not in colloidal condition

Similar experiments have also been carried out by allowing silver nitrate and potassium chloride to react in gelatine It is found that in this case whatever fall in the contact potential is to take place, occurs as soon as silver nitrate in gelatine and potassium chloride in gelatine are mixed, the process not being gradual as in the case of the mixture of silver nitrate and potassium chromate in gelatine Most of the silver chloride in gelatine exists in a condition other than ionic

It is considered that the results obtained from a study of the precipitation of sparingly soluble substances, such as silver chloride, which do not form Liesegang rings in gelatine, should not be applied to explain the condition of sparingly soluble substances, such as silver chromate, which do form Liesegang rings in gelatine There is a difference in the function of the gelatine in the two cases

The results will be discussed elsewhere in detail

Explosions of Hydrogen Sulphide–Oxygen Mixtures

IN the course of an investigation of the kinetics of the reaction between hydrogen sulphide and oxygen at temperatures just below, and up to, that of ignition, an interesting phenomenon concerning the explosion has been observed, which, although in the light of certain recently discovered chain reactions may not be without parallel, yet seems sufficiently striking to warrant mention here

In a cylindrical glass reaction vessel, 3 5 cm in diameter, hydrogen sulphide–oxygen mixtures appear to ignite above about 220° C , though the ignition temperature of course varies somewhat according to the total pressure and relative proportion of the gases used In a similar vessel, 1 1 cm in diameter, no ignition could be observed at 300° C

In a cylindrical vessel of intermediate size, namely, 1 5 cm in diameter, ignition sometimes occurred using higher pressures at 260° C , but generally not below about 270° C The first fact of interest is that the explosions under these conditions were never complete, although when explosion did occur the oxidation was in accordance with the equation

$$2H_2S + 3O_2 = 2H_2O + 2SO_2$$

An induction period of some seconds (or minutes) always preceded an explosion As an example of this, 150 mm hydrogen sulphide and 300 mm oxygen were introduced in this order into the glass vessel at 280° C After 8 seconds induction period (no pressure change) sudden explosion occurred with a pressure decrease of 45 mm If complete explosion had occurred the pressure decrease would have been approximately 75 mm During the 5 minutes following the explosion a rapid reaction occurred with 30 mm pressure decrease In this way the hydrogen sulphide surviving the explosion was finally burnt up in a rapid change On the other hand, if the oxygen–hydrogen sulphide ratio is increased the rapid reaction following the explosion may give way to additional explosions Thus at 280° C :

(1) Hydrogen sulphide, 100 mm , oxygen, 400 mm

0 m	3 s	exploded	25 mm	pressure decrease
0	8	exploded again	15 mm	,, ,,
0	15	,, ,,	10 mm	,, ,,
		Total	50 mm	pressure decrease

(2) Hydrogen sulphide, 196 mm , oxygen, 404 mm

0 m	5 s	exploded, 25 mm pressure decrease	
0	15	exploded again, 16 mm pressure decrease	
0	20	measurable reaction starts	
0	50	additional pressure decrease	10 mm
1	27	,	20 mm
2	18	, ,, ,,	30 mm
3	20	, ,, ,,	40 mm
5	35	, ,, ,,	55 mm
		Total decrease of pressure	96 mm

It is very striking that so many as five successive and quite well-marked explosions have been observed with the same mixture, each being preceded by an induction period which lengthens as the mixture is used up The rise in temperature consequent upon an explosion is never more than 1° C

The nature of the phenomenon and the conditions under which it occurs are to be further examined Meanwhile, a detailed report of the characteristics of the reaction as a whole is in the press , in this a closer discussion of the facts is given

Plankton Changes on the Coast of Ecuador

DURING the month of February of this year an unusual phenomenon has been observed in connexion with the coastal waters of the Pacific from the headland of Santa Elena to the north of Esmeraldas, Ecuador

The normal blue and clear waters of the ocean along the littoral zone have been replaced by turbid, yellowish brown lenses of water which emit a most disagreeable and fœtid odour, suggesting stagnant swamp conditions These discoloured patches, which occur not only along the shore-line but have also been reported in the steamship lanes from Panama southwards, indicate that they have been possibly induced by the equatorial current from the north (El Niño) which, at this time of the year, is found in close association with the cooler Antarctic Current (the Humboldt) The latter, as is well known, impinges upon the greater part of the west coast of South America during many months of the year

An examination of the discoloured water under the microscope has revealed the fact that it is full of plankton material (the greater part consisting of spores of marine algæ), and there is no suggestion of mud or other sedimentary detritus

The idea has been put forward that the normal plankton of the Humboldt Current has succumbed owing to the higher temperature of the equatorial current , on the other hand, it is just possible that the sudden increase in temperature of these waters, caused by the influx of the warm water from the north, may have been responsible for an abnormal

fructification of the larger marine algæ, with a consequent dissemination of spores in sufficient numbers to discolour the water Whatever be the cause, however, the phenomenon is unusual, and has never been noticed by me before during eight years' residence in this part of South America

Disease in Nature

In the review of "The Science of Life", by Wells, Huxley, and Wells, there is a statement on p 479 of Nature of Mar 28, "we are prepared to defend the thesis that wild Nature (that is, apart from man's interference) is characteristically marked by exuberant positive health, while in civilised society diseases are rife and sub health is becoming almost normal!"

The statement is very attractive but, in so far as it refers to plants, is erroneous We are only too well aware of the diseases of crops, but the factors which enter into the problem are not sufficiently understood for us to be able to distinguish clearly between the disease of a crop and the disease of individuals It is a truism that there is a greater opportunity for the spread of disease in crops than in Nature, further, until recently, the cultivation of varieties of crop plants immune to a particular disease received scant attention

The suggestion that trees, herbs, and shrubs growing in their natural habitats are invariably in good health is wide of the mark While it is customary to assume the prevalence of fungal attack in tropical vegetation as visualised by popular writers, it is not perhaps realised that British flowering plants, probably without exception, are parasitised by one or more fungi This parasitism is obviously of different degrees of severity, but it is so general that it has to be taken into account in intensive ecological investigation

No one can doubt that infection with parasites and predatory microbes is common in wild Nature, both among plants and animals, but that is not tantamount to saying that disease is common For disease, whether constitutional, environmental, functional, or parasitic, means disintegrative or deteriorative disturbances of the normal balanced metabolism of the organism Speaking of animals some years ago, the late Sir Ray Lankester said that he knew with certainty of only one microbic *disease* in wild Nature—a bacterial disease of sandhoppers Many parasites—if not most—seem to do little harm to their host, unless that becomes somehow enfeebled, for example, by man's over crowding or over sheltering In many cases, the parasite establishes an innocuous *modus vivendi* with its host, though it may become harmful if man transfers it to a new hospitality Moreover, many so called parasites (the concept has become woolly) are really predatory organisms devouring the plant or animal from within, as a beast of prey does from without Such predatory intruders may destroy the victim, but they do not bring about disease All evidence from crops and plantations and the like must be excluded as irrelevant to my point that wild Nature is characteristically marked by exuberant positive health But this is not to be taken as a dogmatic assertion that there is no disease in wild Nature, and Mr Ramsbottom's expert caveat is very welcome

Extraction of Insulin

In some earlier experiments it was found that insulin was precipitated quantitatively from commercial preparations by means of sulphosalicylic acid and it appeared to us that this fact might form th basis of a method for the extraction of insulin which would obviate the use of large quantities of alcohol

The following is an outline of the technique eventually employed Bullock's pancreas, frozen immediately upon removal from the animal, is minced and allowed to thaw out in about two thirds its weight of 20 per cent sulphosalicylic acid After two hours the whole is filtered in a hydraulic press and the comparatively dry residue covered with acetone and left to dehydrate overnight in the cold The almost water free residue is now extracted in a Soxhlet with acetone and finally dried rapidly in a current of air at 40° The active principle can now be extracted from the powdered fat free residue by 75 per cent alcohol containing about 0 5 per cent of hydrochloric acid The aqueous alcoholic solution of insulin hydrochloride is concentrated in the usual way and the product precipitated with acetone We obtained about 2 gm per kgm of minced pancreas A solution of 0 1 gm of this substance produced, by subcutaneous injection in a 2 kgm rabbit, hypoglycæmic convulsions in five and a half hours

This method, whilst not entirely dispensing with the use of alcohol, requires much less than those in which *fresh* pancreas is extracted We have not explored the conditions for obtaining maximum yield, nor have we the time to do so, but we give the fore going details of a method which, we venture to think, may prove to be of interest to those more actively engaged in the manufacture of insulin

Identification of the Plant called 'Narthex'

In Nature of June 21, 1930, p 920, Mr Henry Balfour inquired as to the nature of the plant called 'narthex' by the present inhabitants of Lesbos Through the kindness of Miss Winifred Lamb, who has been excavating there, it has been possible to identify it with *Ferula communis*, which is the giant fennel and, like a reed, has a hollow stem

This, however, does not definitely solve the point at issue Dr G F Hill points out to me that some of the Cyrenaic coins have represented on them a *Silphium*, which is now extinct and which probably also had a hollow stem For further information the Catalogue of the Greek Coins of Cyrenaica (British Museum), by E S G Robinson (1927), p cclı, can be consulted

N Eumorfopoulos

University College,
Gower Street, London, W C 1

The definite identification of νάρθηκα, as used by modern Lesbians, with the giant fennel, *Ferula communis*, is interesting, and seems to dispose of Theodore Bent's identification of it with a reed The dry pith inside the fennel stalk would, when ignited, continue to smoulder gently inside the protective casing of the stalk, which would prevent the wind causing the pith tinder to be too rapidly consumed Bent's explanation of the νάρθηξ as serving to prevent the smouldering tinder "being blown out", is clearly erroneous I desire to thank Mr Eumorfopoulos for his note upon my communication of June 21, 1930

Henry Balfour

Isomorphism and Chemical Homology

In Nature of Dec 13, 1930, p 916, is a communication by Prof Willy Lange, of Berlin, referring to a letter by me[1] on this subject The misunderstanding can be easily cleared up Dr P B Sarkar has been working in this laboratory for a long time on the chemical homology and isomorphism of complex ions, and his first paper on the subject, on the homology of fluoberyllates and sulphates, was published in 1929[2] In continuation of this work, and proceeding on the basis of Goldschmidt's principles of isomorphism, he was investigating the possible cases of isomorphism among the inorganic complex radicles or ions It was a pure accident that he should have been working on the isomorphism of monofluophosphates and sulphates when Prof Lange's paper appeared in the *Berichte* of the German Chemical Society As in this paper only the simple monofluophosphates and sulphates were described, and crystallographic investigation only of the same was promised, it was not considered necessary to give up that part of Dr Sarkar's work which dealt with the isomorphism of double monofluophosphates and double sulphates, and even then a year was allowed to pass by in awaiting further communication on the subject by Prof Lange As nothing appeared in the interval giving any indication on Prof Lange's part that he would extend his work in this direction as well, I did not consider it justifiable to withhold the publication of this part of Dr Sarkar's work any longer Prof Lange's petition to the Notgemeinschaft der deutschen Wissenschaft on April 29, 1929, regarding the formation of alums by the fluophosphates did not appear in any scientific journal or abstracts, and hence could not attract our notice

However, I deplore the omission of Prof Lange's name in my note, which was not made with any desire to claim priority, complete recognition of his work will be made when Dr Sarkar's work is published in full

The Karoonda (S A) Meteorite of Nov 25, 1930

Following on my letter of last week [see Nature, Mar 14, p 402] concerning the Karoonda meteorite, I now enclose a brief report by Mr A R Alderman, of the Geology Department, University of Adelaide, giving the results of a petrographical and chemical examination made by him of the substance of the meteorite

The final results of the chemical analysis will not be available for some months

Kerr Grant

The University of Adelaide,
Adelaide, Feb 13

The dark greyish interior of the meteorite consists of a dull ground-mass relieved by numerous black chondrules and spangles of a brassy mineral which is probably troilite (ferrous sulphide) The chondrules are very hard and compact and may quite easily be rubbed away from the friable ground-mass by the fingers

Undoubted metallic nickel iron is present in such small amount as to be indistinguishable in the hand specimen

A rough microscopical examination reveals that olivine is by far the most important mineral in the ground-mass Some hypersthene is also present

The chondrules consist of these minerals with a good deal of glassy material Minute granules of nickeliferous iron are but rarely seen, but grains of an opaque brassy mineral are of very variable size and are apparently troilite

The chemical analysis (not yet completed) is in agreement with the mineral composition Silica is very low, about 34 per cent, whereas in the silicate material ferrous iron is present in greater amount than is magnesia

An accurate estimate of the percentage of metallic material is not yet available, but it seems probable that metallic iron constitutes less (possibly much less) than 0 3 per cent of the specimen analysed Nickel is of the order of 0 03 per cent

Medicinal Cod Liver Oil

In our recent Report to the Empire Marketing Board on the Relative Values of Cod Liver Oils from Various Sources (E M B 35), noticed in Nature of April 4, p 538, an unfortunate blunder has arisen during the revision and proof reading of the introductory chapter

Reference 6 on page 9 is incorrectly given and should, of course, refer to the important paper by Prof Steenbock and his colleague Dr Boutwell in the *Journal of Biological Chemistry*, vol 42, p 131, 1920

Immediately our attention was directed to the error we wrote to Prof Steenbock expressing our great regret and, although he desired that we should give no further attention to the matter, we feel that we must override his wishes and make public our correction of the mistake

On the same page the reference to Prof E Mellanby's pioneer researches on the causation of rickets might suggest that his results were not published before 1921 We were, of course, well aware of his earlier contributions to the subject but thought it better, in a brief summary, to refer the reader to the full account of his earlier work which was published by the Medical Research Council

We would like to express our apologies to these distinguished investigators

Atomic Weight of Krypton

While measuring the dielectric coefficient of a particularly pure sample of krypton, it occurred to me that a density determination would be of interest in view of Aston's recent statement that the accepted value of the atomic weight appeared from his measurements on the relative quantities of the isotopes to be much too low

I made a comparison of the densities of krypton and oxygen by means of the microbalance and found that at 25° the pressures at which the two gases had equal densities were 301 15 mm and 787 8 mm If the compressibility corrections were proportional for the two gases, the atomic weight of krypton would be 83 71, while using the most probable value for the compressibility of krypton which I calculated in 1910, the figure reduces to 83 62

While these results must not be considered final, it appears highly probable that Aston's figure 83 77 is more accurate than the accepted 82 9

The New Crystallography

By F. I. G. Rawlins

THE attraction which the study of crystals has always exerted, not only upon the scientific worker but also upon a wider circle, is in no danger of abating. The time is perhaps appropriate to discuss a number of developments which have come about during, roughly, the last five years. So far as the crystalline state itself is concerned, the chief change has been one of classification; it is not necessarily the crystal system which determines much of our present-day knowledge, but rather the atomic environment. Thus, in rock salt, each atom (or more strictly, ion) of sodium is surrounded by six ions of chlorine at the corners of an octahedron, and conversely. From the experimental point of view, this advance must be placed to the credit of the X-ray workers; it has only comparatively recently been recognised, however, that upon the structures thus established it was possible to build up a systematic chemistry of the solid state, based upon the conceptions of environment, ionic size, and ionic deformability.

It has come about that a considerable part of the subject of crystallography is concerned with the question: Given the structures of a large and increasing number of elements and compounds, how much can be deduced about their physical and chemical properties? And again, one asks what kind of experiment is most likely to provide this information, and whether it is essential to work with crystals at all in some instances. These queries are easily seen to reduce to this: whether it is desired to know something about the crystalline lattice, or whether it is the components of the lattice that are the more important. Research of the former kind obviously needs actual crystals, whereas the latter may be able to make some progress in states of matter wherein lattices, as ordinarily understood, do not exist: for example, solutions and even gases. Clearly, the new crystallography will trespass upon the preserves of many neighbouring sciences.

The Union of Ions into Crystals.—From a logical point of view, it is not altogether fortunate that so much attention has been given for so many years to the morphology of crystals as such. A more fundamental way to proceed would be to consider a free atom of an element A at some distance from a free atom of some other element X, and to follow the course of events in which all the A's and all the X's are bound so that the assemblage $\Sigma [A, X]$ is in equilibrium, at a temperature such that the components A and X are constrained to fulfil certain definite geometrical conditions with respect to each other. Stability will ensue for that particular configuration of $\Sigma [A, X]$, say $S [A, X]$, for which the energy is a minimum. In other words, the arrangement $S [A, X]$ represents a crystal.

This view has led to some very interesting results in a series of experiments upon the alkali halides. The ionic refractivity, which depends upon the deformability already mentioned, can be measured in the free state, R (free ions), and in the crystalline state, R (solid). Now, cations and anions behave very differently in the presence of each other. Anions are consolidated, or rendered more rigid, by neighbouring cations, because in addition to the attraction of the nucleus of the anion for its own electrons, there is added that of the positive cation. A similar argument shows that just the reverse holds for a cation under the influence of an anion—the distortion or deformability increases. Hence, in the former case the refractivity decreases, and in the latter it rises. Thus the union of ions to form a crystal will bring about a net decrease in refractivity when the consolidating effect of cations upon anions preponderates over the loosening effect of the anions upon the cations, and vice versa. For most of the alkali halides the difference R (solid) $- R$ (free ions) is negative, which corresponds to a net consolidation when the crystal is formed out of the appropriate free ions. Only for potassium and rubidium fluorides (KF and RbF), in which a large ion is paired with a small ion, is a net loosening indicated. A balance is approximately obtained for sodium fluoride (NaF) and rubidium chloride (RbCl): the experimental accuracy is not high enough to detect very small differences in the refractivities.

In aqueous solution the refractivity is found to vary with concentration in a manner which suggests that at high concentrations the ions approach each other nearly as closely as in the crystal lattice; they are in direct contact, with no intervening water molecules. Other examples of relationships between crystals and solutions will occur later; they have been fairly extensively studied by spectroscopic methods.

Crystal Thermodynamics.—Strictly, thermodynamic reasoning is independent of a mechanism, and in this sense its application to crystal lattices and the particles composing them is not very obvious. Nevertheless, an extension of its proverbial boundaries has extended our grasp of the energetics of the solid state. To show how this has happened, two examples, characteristic of the most modern work, will be discussed. In the first, one is dealing with a sub-lattice property, and in the second, with a lattice property. Consideration in this particular order will serve to stress the general outlook of this article; the units composing a crystal are, from this aspect, of prior importance to the particular way in which they may be grouped.

The quantum theory, applied to gaseous molecules, has been fruitful in unravelling the complexities of rotational and vibrational motion. The latter has long been recognised to be characteristic of the solid state also, but it is only very recently that the possibility of molecular rotations in crystals has been seriously considered. The work is for the most part theoretical, and based upon suitable applications of the wave mechanics to diatomic molecules. The wave equation appears in the form of Mathieu's equation, and the corresponding energy levels are generally readily deducible

Analysis shows that two extreme cases may be discerned, one in which the energy equations are those of the quantised harmonic oscillator, while the other approaches the value for the rotator. The next step is to obtain a discriminant, in terms of measurable quantities, for the transition between oscillational and rotational motion. The inequalities

$$n+1<\beta\nu/4\theta \text{ (oscillational)},$$
and
$$n+1>\beta\nu/4\theta \text{ (rotational)},$$

provide, on certain assumptions, the criterion desired, for the quantum state n and frequency ν. The factor θ depends upon the moment of inertia, which is readily forthcoming from spectral data, while β is a constant. Another, and in some respects a simpler analysis, demonstrates that rotation may be expected at temperatures greater than $2V/k$, and oscillation for values less than this fraction (V is a characteristic quantity in the potential function for the particular molecule considered, and k is Boltzmann's constant). The probability that a molecule will rotate is capable of approximate calculation, yielding $P=e^{-2V/kT}$, where T is the temperature.

The expressions in terms of n and θ can conveniently be combined into the equation $n_0+1=\beta\nu/4\theta$, where n_0 is the particular value of n, which is on the borderline between the rotational and vibrational states. For hydrogen (H_2), with its small moment of inertia, $n_0+1\sim 0.4$, whereas for iodine (I_2) $n_0+1\sim 350$. From these figures, it follows that the molecules in solid hydrogen are rotating even in the lowest quantum states, whereas in iodine no molecules are rotating in the crystal, since melting occurs for $n\sim 12$.

The ammonium salts provide an interesting example of substances for which the transition from rotation to vibration may be expected to set in well within the solid range. A temperature of about 240° absolute is indicated by the theory. Observations of the heat capacity as a function of temperature have shown that in a number of substances there is a finite range of temperature over which the relative numbers of molecules in either state is undergoing a progressive change.

The second contribution, already alluded to, concerns the form of the specific heat curve (particularly at low temperatures) as a function of the crystal symmetry of the substance. If one assumes that the usual Debye equation represents the facts for the cubic system, then, as materials of decreasing symmetry are examined, instead of following the 'ideal' curve (convex upwards), an approximately straight line results. The sequence is well seen in the series zinc sulphide (cubic), zinc oxide (hexagonal), cupric oxide (triclinic). The importance of this effect is that the specific heat is influenced by the atomic environment, a typical lattice property.

Crystal Spectra.—As in the thermodynamical matters already discussed, it is convenient to divide crystal spectra into two main classes, those of ionic (or even sub-ionic) origin, and those for which the lattice, or at least parts of the complete lattice, are responsible. In dealing with the former, one is tempted to make a yet finer distinction between the types of spectra in which ions, or groups of ions, are concerned (in contradistinction to the swinging of large portions of the whole lattice), and phenomena which have their seat within the ion itself: that is, transitions of an electronic nature. Spectra arising from these three causes may be expected to appear at increasing wave length as the mass of the unit concerned increases. Thus, sub-ionic (electronic) absorption spectra in crystals may occur in the visible region, and are closely connected with the nature of colour. Inter-ionic spectra are found in the near infra red (between about 1μ and 30μ); lattice spectra are revealed at a wave-length some ten times greater, and are usually detected by the method of residual rays, or some system involving focal isolation. Oscillations of approximately these frequencies are those encountered in the theory of specific heats already mentioned.

In electronic crystal spectra, restricted in the main to salts of the rare earths and those of the transitional elements, one is confronted with a problem of great complexity, intimately connected with electronic levels and the magnetic properties of ions with incomplete electronic shells. There is little doubt that the sharpness of the bands in the visible region is attributable to the high electrostatic shielding and weak coupling between the electrons belonging to neighbouring ions. Information of value to chemists may well be obtained by studies of this kind.

Somewhat similar investigations have produced some illuminating results when the absorption spectrum of an ionic group like MnO_4 is examined in a crystal and in solution. The effect of dissolving, say, potassium permanganate, in water is to slow down the oscillations characteristic of the group, owing to the outward pull of a solvent of high dielectric constant ($=80$): solution in ethyl acetate (D.C. $=6$) allows the MnO_4 group to contract to almost the same dimensions as it has in the crystal lattice of potassium permanganate. In other words, the surrounding molecules of ethyl acetate have much the same effect upon the MnO_4 tetrahedron as the ions of potassium in the solid state.

It is natural to infer from this that much might be gained by careful study of the dielectric constants of crystals, especially at temperatures immediately below the melting point. Much the same applies to observations of absorption spectra in crystals at different temperatures. A promising start has already been made at the low temperature end, but the technical difficulties are great, and the results will need much skill to interpret.

No attempt has been made to discuss the Raman effect in relation to crystal physics and crystal chemistry: already the literature is voluminous, and the significance of some of the results by no means clear. The method is certainly of great value. Statistical mechanics may be expected to play a considerable part in the future development of the new crystallography; in fact, all the resources of modern science can contribute something to our knowledge of the solid state.

The First Sugar of Photosynthesis and the Rôle of Cane Sugar in the Plant

PHOTOSYNTHESIS, upon which all living organisms depend directly or indirectly for their existence, is still imperfectly understood We know that the green plant takes in its carbon in the form of the carbon dioxide of the air, and we also know that carbohydrate appears in the leaf, as the result of the fixation of the carbon through the action of the sun's rays with the chlorophyll The intermediate stages are still a matter of conjecture

The formaldehyde hypothesis of Baeyer put forward so long ago as 1870 still awaits clear proof Supposed conclusive evidence in its support has from time to time been advanced , but on critical examination has proved unacceptable This has happened in a recent attempt to establish the validity of the theory Klein and Werner [1] using the delicate test of dimedon for aldehyde were in a measure convincing Barton-Wright and Pratt,[2] however, in repeating and checking their work, now show that the formaldehyde detected in the experiments is due to the action of light on carbon dioxide and bicarbonates, and is independent of the photosynthetic mechanism of the living plant They sum up the matter thus "Although the formaldehyde hypothesis has the merit of simplicity, which has probably been the prime cause of its wide popularity, no work has as yet convincingly shown that formaldehyde is produced normally in the green leaf or that it plays any part in the photosynthetic process of the living plant"

This statement is perhaps a little too sweeping As formaldehyde is toxic to the plant, it is scarcely to be expected that it should accumulate in the free state in an appreciable amount under normal conditions It may be assumed that, as soon as the reduction of the carbonic acid takes place, the aldehyde formed is at once polymerised to sugar

The important work of Baly on photosynthesis *in vitro* is here relevant He has shown recently [3] that when a solution of carbon dioxide is exposed to ultra violet light, formaldehyde is first formed and then sugar But when a coloured catalyst, such as cobalt or nickel carbonate, is present, the action takes place in ordinary light with the direct production of sugar, no aldehyde being detected Something analogous may therefore take place in the green leaf The magnesium of the chlorophyll may be the active metal concerned Hence on such a supposition it will be futile to search for free aldehyde in assimilating leaves

In respect of the generally accepted view that some form of carbohydrate is the final product of carbon assimilation, the question as to the exact nature of this is still not completely answered The classical experiments of Sachs conducted from 1862 onwards proved conclusively that the starch grains, which appear on the chloroplasts of the leaf when exposed to light, are the direct result of the fixation of carbon Starch thus became known as the first visible product of assimilation It was assumed that sugar, probably glucose, preceded the formation of starch

Brown and Morris were the first to undertake elaborate estimations of the carbohydrates contained in foliage leaves From their investigation of the carbohydrates in the leaf of the garden nasturtium (*Tropæolum majus*),[4] they concluded that cane sugar (sucrose) is the first carbohydrate to be set free in photosynthesis This was an unexpected and novel idea, as sucrose, being a disaccharide, had hitherto been regarded more in the light of a reserve carbohydrate They essayed a formidable task—a pioneer effort to estimate separately in the leaf four sugars (sucrose, maltose, dextrose, and levulose) as well as starch The hydrolytic product of the starch complicated the issue Monocotyledons, as a whole, in contrast to dicotyledons, form little starch in their leaves in normal circumstances, and some none at all In following up Brown and Morris's work, Parkin, in order to simplify the problem, chose one of the latter, namely, the snowdrop [5] He found he had only three carbohydrates with which to deal, namely, sucrose and its two hexose derivatives, dextrose and levulose He interpreted his results likewise in favour of sucrose being the first sugar liberated, and he regarded the two hexoses as arising from it through inversion

The Rothamsted workers, Davis, Daish, and Sawyer, were the next to take up the subject They advanced this side of biochemistry considerably by pointing out weaknesses in former methods and by elaborating new ones of extraction and analysis They investigated in detail the carbohydrates of the mangold and potato leaf,[6] and in their conclusions also support the view that sucrose is the first sugar of photosynthesis

Now the pendulum is swinging the other way Two important papers, by Clements [7] and by Barton Wright and Pratt,[8] published last year, both favour the view that glucose (dextrose) is the first sugar to be liberated—a view, of course, more in harmony with Baeyer's hypothesis and also with chemistry generally These investigators have carried out estimations at hourly intervals during both day and night—an advance upon what has been previously attempted

Clements, an American worker, took for his research the leaves of the sunflower, the potato, and *Soja max* Barton-Wright and Pratt, of Great Britain, selected the daffodil, which normally does not produce starch in its leaf Their results are therefore comparable with those of Parkin on the snowdrop In some respects they confirm the latter's work, though as regards the first sugar of photosynthesis they argue cogently for the opposite view

Methods of analysis are naturally of prime importance in work of this kind Each fresh investigator generally manages to bring to light flaws in previous methods The Rothamsted workers with all their care are shown by Barton-Wright and Pratt to have overlooked a point which may have seriously prejudiced their figures for the hexose sugars They find that the alcoholic

extraction method used by Davis, Daish, and Sawyer results in the formation of appreciable amounts of aldehyde, and this affects considerably both the cupric reduction and the optical rotation

Such work as has been quoted sheds no light on the exact position of the various sugars in the leaf Strakosch some years ago applied certain micro-chemical tests to the assimilating leaf, and found hexose as the only sugar present in the palisade cells, but the reliability of his method is open to question The work of Weevers on variegated leaves, published in 1924, is probably of greater value in support of the glucose view He found both hexose sugars and sucrose in the green parts, but only sucrose in the white portions of the leaf

The balance of evidence at the present time would seem to be in favour of the original supposition that glucose is the first sugar to be set free in photosynthesis On the alternative view, the two hexose sugars are easily accounted for as the inversion products of the sucrose But on the assumption that glucose appears first, then one has to imagine that part of it is first changed to fructose (levulose), and that from these two hexoses sucrose is synthesised If these transformations do take place in the leaf, we are at present quite ignorant as to the means by which they are brought about

Whatever may be the carbohydrate sequence in photosynthesis, there is cumulative evidence pointing to cane sugar as of wide, if not of universal, distribution among the higher plants Apparently it is of fundamental importance, since no matter what form the carbohydrate may take in the seed or reserve organ, sucrose soon makes its appearance on germination The evidence is increasing that carbohydrate can travel largely in this form Mason and Maskell's important work on the cotton plant [9] favours this Then, again, as a rule, leaves when fed with sugar solutions form starch more readily from sucrose than from any other sugar Notwithstanding this apparent desire of the plant to have its carbohydrate in the form of sucrose for circulatory and metabolic purposes, there is no important reserve carbohydrate which yields cane sugar directly by enzymatic action [1]

In view of the fact that starch, the commonest of reserve carbohydrates, yields maltose when acted upon by its enzyme, diastase, this disaccharide rather than sucrose might have been expected to be chiefly evident in plant tissues, but it is not so It may be that a non reducing disaccharide is desired Maltose has reducing properties, but sucrose has not Then it has been suggested that the two hexose sugars, dextrose and levulose, which arise from the sucrose through inversion, may play different rôles in metabolism Further, it is possible that these hexoses are more active when in the nascent state, that is, at the moment of their formation from sucrose through hydrolysis This would account for cane sugar being found in meristematic tissue, upon which Priestley [10] laid stress a few years ago J P

Obituary

PROF HUGH RYAN

BY the death on Mar 27 of Prof Hugh Ryan at the age of fifty-eight, Irish chemists have sustained a loss which they will feel for many years to come

Hugh Ryan was educated at Blackrock College, Dublin, and received his earlier chemical training under Prof A Senier in Queen's College, Galway Graduating in 1895, he obtained the M A degree, with gold medal, in 1897, and then proceeded to Berlin, where he engaged in research under Emil Fischer and Siegmund Gabriel Returning to Dublin in 1899, he was appointed professor of chemistry in the Catholic University School of Medicine and in University College, St Stephen's Green, Dublin In the same year he was awarded the D Sc degree and appointed fellow of the Royal University of Ireland On the foundation of the National University of Ireland in 1908, Ryan became professor of chemistry in University College, Dublin, a position which he occupied until his death In 1924 he was appointed Chief State Chemist in the Irish Free State and was responsible for the organisation and control of the State Laboratory

Throughout the entire period of his association with university teaching, Ryan devoted a large part of his time to research and published more than seventy papers In his earlier work, influenced by his period with Fischer, he was engaged on the synthesis of glucosides His researches in this direction, carried out under the most discouraging conditions, display his extraordinary enthusiasm and skill as a chemist With the erection of the new buildings of University College, Dublin, under the Irish Universities Act of 1908, he had, for the first time, adequate laboratory equipment, and his remarkable powers as an organic chemist were given fuller scope There followed a series of researches on the constitution of certain waxes and the preparation of a number of compounds allied in character to the colouring matter of turmeric Further papers dealt with the synthesis of natural organic colouring matters and the preparation of derivatives of diflavone, diflavanone, and dicoumaranone At the request of Nobel's Explosives Company, he undertook investigations on the mode of action of stabilisers in propellent explosives, the results of which were of the greatest value Numerous other papers discussed the condensation of aldehydes with ketones and the structure of catechin Ryan's many activities included a profound interest in Irish peat industries, and on this subject he furnished a very complete report to the Royal Dublin Society

While his main interests lay in the direction of organic chemistry, the extraordinary breadth of Ryan's knowledge of all branches of chemistry always aroused the admiration of his colleagues, both in Great Britain and Ireland. To Irish men of science his great achievement was that he created in Dublin, from small beginnings and almost unaided, an important school of research in chemistry. The range of his influence in this respect, already widely felt, will be more fully appreciated in the future.

In public and private life Hugh Ryan was a most lovable and sterling character, with a rare simplicity and charity of outlook. His untimely death will cause genuine grief among the many students of science, engineering, and medicine who received instruction from him. J. ALGAR.

WE regret to announce the following deaths:

Dr. T. V. Barker, secretary to the University Chest in the University of Oxford, author of numerous books and papers on mineralogy and chemical crystallography, on April 15, aged fifty years.

Prof. E. P. Culverwell, senior fellow and professor of education in Trinity College, Dublin, who was known for his work on the calculus of variations and mathematical and physical theories of the Ice Age, on April 17, aged seventy-five years.

Prof. J. Lorrain Smith, F.R.S., professor of pathology and dean of the faculty of medicine in the University of Edinburgh, on April 18.

The Ven. J. M. Wilson, sometime canon of Worcester and headmaster of Clifton College, who was a member of a British Association committee on science in schools so long ago as 1866, on April 15, aged ninety-four years.

News and Views.

THE preliminary programme has now been issued of the centenary meeting of the British Association, to be held in London on Sept. 23–30, under the presidency of the Right Hon. J. C. Smuts. So far, of course, only the barest outline of the proceedings is possible, but it is clear already that the meeting is going to be worthy of the occasion. The reception room and offices for the meeting will be in the University of London (Imperial Institute Road, South Kensington). General Smuts will assume office at a meeting in the afternoon of Sept. 23 in the Albert Hall, where the Faraday Centenary Exhibition is being held, and will deliver his presidential address on the same evening at the Central Hall, Westminster. Special tickets will be required for General Smuts's address; arrangements are being made for relaying it to other halls if necessary. Evening discourses will be given by Prof. W. A. Bone (photographic analysis of explosion flames), Sir P. Chalmers Mitchell, Sir Arthur Keith, Sir Oliver Lodge (a retrospect of wireless communication), Sir William Hardy, and Sir James Jeans. The Huxley Memorial Lecture of the Royal Anthropological Institute will be delivered on Sept. 29 by Dr. G. Thilenius, and members of the Association are invited. Various public lectures will be given in certain polytechnic institutions in London. It is expected that receptions will be given on Sept. 24 by the Royal Society, in connexion with the Faraday celebrations, and on Sept. 25 by H.M. Government. Exhibits and demonstrations are again being arranged by the British Broadcasting Corporation. London and its neighbourhood will provide plenty of opportunities for sectional excursions. Down House, Darwin's home for many years and now in the care of the Association, is within easy reach, while an invited party will visit York, the birthplace of the Association, on Sept. 26–27. Preceding the meeting will be a geological excursion to East Anglia on Sept. 16–22, and those wishing to take part are requested to communicate with Mr. I. S. Double, University, Liverpool, as soon as possible.

THE formative influence upon the teaching of science in schools which was exerted by Canon J. M. Wilson, whose death has recently occurred, was evident so far back as 1866, when he was a member of a committee with Dean Farrar, Prof. T. H. Huxley, and Prof. J. Tyndall, appointed by the British Association at its meeting at Nottingham, "To consider the best means of promoting scientific education in schools". The report of this committee was issued in 1867 and laid stress on science as an essential subject in the curriculum, not necessarily to train physicists and chemists but as an effective instrument in mental development. The subjects suggested in the report were elementary physics, elementary chemistry, and botany. Canon Wilson, in a paper on "Teaching Natural Science in Schools", published in 1867, gave an account of methods adopted in introducing science teaching in Rugby School. He selected botany as the best subject for beginning to train boys in scientific method. This was followed by experimental physics. By his choice, he seems to have anticipated the present-day position of botany in the school curriculum, at any rate, from the theoretical point of view. There is much discussion on the position of botany, or elementary biology, in the school curriculum, but there is still much to be done in a practical way. There are comparatively few secondary schools, especially for boys, where science is introduced by botany or biology, as it was sixty-five years ago under Canon Wilson at Rugby. The sole idea in Canon Wilson's mind was to train independent observation and reasoning, not to supply the biology 'demanded' by the first examination for medical and dental degrees and diplomas, which some of our public and secondary schools are now doing with not quite satisfactory results.

ON April 28, one hundred years ago, the eminent mathematician and physicist, Peter Guthrie Tait, was born at Dalkeith. Educated at Dalkeith Grammar School and the Edinburgh Academy, in 1847 he entered the University of Edinburgh and the following year became an undergraduate of Peterhouse, Cambridge. At the age of twenty-one, he graduated as Senior Wrangler, being the youngest on record. He was also Smith's prizeman. Two years later he was appointed professor of mathematics in Queen's College, Belfast, having Andrews for one of his

colleagues In Ireland he also made the friendship of Sir William Hamilton, through whom he became the great exponent and advocate of quaternions After four years at Belfast, Tait was chosen to succeed J D Forbes as professor of natural philosophy in the University of Edinburgh, and this post he held with great distinction until the year of his death, which occurred on July 4, 1901 His biographer gives a list of 22 volumes and 365 papers written by him alone or in collaboration with others Most famous of all is the "Treatise on Natural Philosophy", written jointly with Sir William Thomson, afterwards Lord Kelvin, and generally referred to as "T and T[1]" This work, it has been said, takes rank with Newton's "Principia", Laplace's "Mécanique céleste", and Maxwell's "Electricity and Magnetism" Other works included Tait's "Thermodynamics" (1868), "Heat" (1884), "Light" (1884), and "Properties of Matter" (1885) He also translated Helmholtz's "Vortex Motion" and Mohr's "Views on the Nature of Heat"

Two volumes of Tait's scientific papers were published in 1898 and 1910, and his biography by Prof C G Knott appeared in 1911 His portrait was painted three times by Sir George Reid and the pictures are to be seen at Peterhouse, the Royal Society of Edinburgh, and the Scottish National Portrait Gallery respectively As a professor, he was distinguished by his earnest attention to the duties of his chair and by his capacity of inspiring his pupils with both enthusiasm and affection He was as successful in presenting the elemental or fundamental truths of science as he was in advancing its range and attacking new problems A keen golfer and able to apply mathematical analysis to the flight of a golf ball, on one occasion when staying at St Andrews, his guest, Helmholtz, then about fifty years old, wrote "Mr Tait knows of nothing else here but golfing I had to go out with him, my first stroke came off—after that I hit either the ground or the air Tait is a peculiar sort of savage, lives here, as he says, for the muscles, and it was not till to day, Sunday, when he dare not play and did not go to church either, that he could be brought to talk of rational matters" With Balfour Stewart, however, Tait published a book on the "Unseen Universe" which, while it called forth praise and censure, fulfilled the authors' purpose to show that the common statement that "Science is incompatible with religion" was baseless Tait's correspondents included Kelvin, Maxwell, Cayley, Hamilton, and many other scientific men of the Victorian age

THE Paris correspondent of the *Morning Post* states, in the issue of April 10, that news has been received in Russian circles in Paris that Profs Michaelovsky and Saposhnikoff have been arrested and exiled to the far north of Russia The reasons for their arrest and exile are unknown in Paris Prof Saposhnikoff is well known in scientific circles in Great Britain and this news will cause much sorrow to his friends here He was frequently in England and took part in the International Congress of Applied Chemistry held in London in 1909 He also spent considerable time in Great Britain during the War, and for his services at that time he was made a Knight Commander of the Order of St Michael and St George In the early days of the revolution, Prof Saposhnikoff was imprisoned for several months in Petrograd and his two sons were shot After his release he held several important posts and visited the Continent and England on official business for the Soviet Government He was professor at the Michael Ordnance Academy and also at the Institute of Roads and Communications He was a diligent worker and published much work of scientific value

PROF SAPOSHNIKOFF is a pioneer in the chemistry of explosive substances His work on the decomposition of nitrocellulose and his investigations in connexion with the nitrating properties of nitric acid in sulphuric acid with reference to the vapour tension of the mixture were acknowledged as important contributions by all explosives chemists He worked on a variety of other subjects of purely scientific interest and was also the author of a number of papers on metallurgy, including investigations on the microstructure and physical properties of alloys His papers during the period 1903 12 occupy a column in the index of the *Journal of the Chemical Society* The results of his investigations appeared in Russian, German, and French journals, and since the War he has contributed many papers on scientific and technical subjects, which have been published in Russia Prof Saposhnikoff is sixty three years of age and has a record of highly valuable scientific and technical work which is recognised and appreciated by all scientific workers in Europe It is little short of disastrous that the world, as well as Russia, should be deprived of the services of a man who is still capable of doing excellent work for the benefit of humanity

IN our issue of April 18, p 600, we printed a very brief account of the history of the Paris Observatory, prompted by the reports in the daily press that the Observatory was closing down and that a new national observatory was to be built in the Durance region of Provence These reports, it seems, are incorrect and we much regret having given them further currency by repeating them M Ernest Esclangon, Director of the Paris Observatory, has written explaining the present position and prospects of the Observatory, and we cannot do better than reproduce his words "Il n'est nullement question d'abandonner l'Observatoire de Paris, bien au contraire Nous demandons seulement qu'une grande succursale de cet observatoire soit créée en Provence où le ciel est particulièrement beau, cette succursale serait dotée d'instruments puissants et modernes, notamment de grands télescopes L'Observatoire de Paris garderait toute son importance, un grand nombre de services d'observation y seraient conservés, notamment le service méridien, le service de l'heure, le service des équatoriaux pour les observations d'étoiles doubles, le service des observations solaires installé à Meudon, etc En outre, l'Observatoire de Paris centraliserait les

documents que les astronomes iraient recueillir dans la succursale en Provence, étudierait ces documents, en tirerait les conclusions, en un mot, l'Observatoire de Paris, en plus des services d'observation qui y seraient conservés, constituerait comme le cerveau de l'organisation d'ensemble Mais au surplus, tout cela reste pour le moment à l'état de projet, et aucune décision n'a pu être prise puisque les crédits nécessaires pour cette réalisation ne sont pas encore votés, et qu'actuellement, nous ne disposons pas des moyens pécuniaires indispensables pour mettre ce projet à exécution " We welcome this very clear statement by M Esclangon and trust that funds will be quickly forthcoming to enable the realisation of the scheme he has outlined

THE official report on the Hawkes Bay earthquake of Feb 3 has been received from Lord Bledisloe, Governor General of New Zealand The loss of life (212 persons) was due mainly to the fact that the centre of the earthquake—somewhere beneath the Pacific Ocean—was not far distant from two towns, Napier and Hastings, containing between them a population of about 35,000 The shock was felt over a great part of the North Island and the northern district of the South Island, while the area over which material damage occurred extends from near Gisborne on the north to Waipawa on the south, and from Tarawera on the west to the Pacific Ocean The houses that generally withstood the shock were those of wood or reinforced concrete Brief but interesting accounts of the Murchison earthquake of June 17 1929, are contained in the Report of the Dominion Astronomer and Seismologist for the year 1929 and in an article on the "Seismology of New Zealand", published in the *New Zealand Official Year book* for 1931 The map of the isoseismal lines shows that, except for very small areas in the extreme north and south, the earthquake was felt throughout both islands The movement along a fault near Murchison raised the ground on the east side about fifteen feet and shifted it about nine feet to the north west Recent levellings show that the block is now sinking back somewhat irregularly, a movement that is no doubt responsible for the after shocks felt so frequently in the central area Of these, no fewer than 632 were recorded by the end of the year at the Wellington Observatory

THE annual exhibition of the Television Society was held on April 15 at University College, London The number of exhibits was greater than in previous years The trend of development is in the direction of large screens with projection methods suitable for large audiences The Tuke cup was awarded to R Wilson and A A Waters for an excellent television equipment with a mirror drum receiver and screen projector In this system the person being televised is not dazzled by excessive light, and he can be seen at the same time as the image on the screen It worked very satisfactorily, and the receiving set is small and quite ornamental, which we consider a great step in advance In television between places about a hundred miles apart, 'echo images' are sometimes observed, one image being partly superposed on the other T H Bridgewater showed how this phenomenon can be used to determine the height of the Kennelly-Heaviside layer The research laboratories of the General Electric Co showed two gas discharge tubes which operate directly from the 200 volt alternating current mains without using high tension transformers The sodium tube gives a yellowish light and the neon mercury vapour in a uranium glass tube gives a bluish white light We were impressed by the educational exhibits Printer's blocks were prepared showing the amount of definition possible by different television scanning systems, and simple diagrams illustrated the underlying principles of television The G P O exhibited excellent photographs received in Great Britain from Austria, Denmark, Germany, and Sweden by the Siemens Karolus Telefunken system The British Stenode Radiostat Corporation showed various stenode models of radio receivers of very high selectivity

As there is little more than one per cent of the world's main line railways electrified, there is plenty of scope for electrical engineers to convince the railway companies of the advantages of electrification There is general agreement that suburban and tube railways should be electrified Where the trains are continually starting and stopping, electrification enables the lines to carry far more passengers and to accelerate the service In underground tunnels and in tube railways, the noxious vapours generated by steam trains makes electrification compulsory After the War the Austrian Government obtained an international loan, a part of which it set aside for main line electrification In 1927, however, the work was stopped and the money used for other purposes Large portions of the scheme were therefore left unfinished One of the reasons was the lowering of the price of imported coal, and another was possibly that too favourable a view had been taken of the costs of electrification In *World Power* for March, Dr M G Say discusses these aspects of railway electrification Main line electrification is not favoured in Great Britain because coal is cheap, the gradients are seldom severe, and there are scarcely any main lines where the tunnels render steam haulage hazardous The London Brighton line, 51 miles in length, will be the longest electrified route in Great Britain It will be worked by multiple unit trains of six coaches The present steam train service of two million train miles per annum will be replaced by an electric service of nearly five million train miles The conversion cost is estimated at about £50 000 per mile, and energy outside the London area will be obtained directly from the national grid network The maximum speed of 65 m p h will enable the quickest trains to have an average speed of 54 m p h If this line is successful, it will probably be the forerunner of further electrified zones eastwards and westwards from Brighton and Worthing

THE first and the most useful of the commercial applications of radio communication was to marine navigation In his chairman's address to the wireless section of the Institution of Electrical Engineers,

published in the March number of the *Journal* of the I E E, C. E Rickard gives interesting data of the progress that has been made The international legislators who frame the rules and regulations for wireless communication insist that marine radio telegraphy shall progressively improve and, so far as economically possible, keep in step with modern progress About fourteen thousand of the world's ships are now fitted with wireless apparatus Of these, about ten per cent are fitted with valve transmitters and the rest with spark only Spark transmitters of 100 watts input power are generally considered to provide the best form of emergency apparatus, probably because it is thought that a strident and hoarse cry for help will attract the most attention By the new international regulations, no spark transmitters of greater power than 300 watts input power are to be installed From now onwards, therefore, the percentage of high power spark stations on board ship will steadily decrease There are about twelve thousand ships fitted with automatic alarm devices which enable a ship's operator to be called to his post when he is not on watch At the end of last year, about five hundred ship's lifeboats were fitted with wireless Vessels of less than 1600 tons gross tonnage which do not carry passengers are under no legal obligation to have radio apparatus Many of them, however, are fitted with radio, as it is found of great value not only in navigating the ship but also in carrying on their business In particular, trawlers, whalers, and other vessels connected with the fishing industry are generally equipped with radio There are now more than 200 automatic radio beacons around the coasts of the leading maritime countries of the world

THE new Welland Ship Canal between Lakes Erie and Ontario, which was opened on July 1, 1930 (NATURE, July 5, 1930, p 30), allows vessels of ocean liner size to pass round Niagara Falls and removes one of the two great barriers that have kept deep sea shipping out of the Great Lakes Between the lakes and the ocean only the barrier of the Lachine Rapids, round which smaller vessels alone can pass, remains But the largest lake vessels, about 600 feet in length, are now able to get into Lake Ontario There are 21 electric drawbridges over the new canal, some of them spanning the canal's full width of 320 feet Unlike the Panama Canal, where only the locks are illuminated, the entire length of the canal is lighted like a city street The Welland locks are tremendously deep Three of them give a total lift of 140 feet in less than three quarters of a mile The electrical equipment is built by the Canadian Westinghouse Co, Ltd The locks have corridors, steps, and electrically lighted mooring platforms, half way down the sides The attendants check the way of the ship as it sails in at the lower level As the water comes in, the men retreat and the lock is flooded The electric lamps in their water tight globes are left burning far underneath the water One end of the canal is 326 feet higher than the other If it were not for the lock-gates, Lake Erie would run into Lake Ontario, forming a new Niagara Falls In the unlikely event of a lock-gate failing, there is a boat with powerful hoisting gear always ready to plug the canal by an emergency gate

A CONFERENCE of teachers and other professional experts in prehistoric archæology will be held in Bern in May, at the personal invitation of Prof Bosch-Gimpera, of Barcelona, to discuss the future organisation of prehistoric studies This conference arises out of suggestions which were discussed at the Congress of Archæology held at Barcelona in 1929, when the question was raised whether, in view of the situation which had arisen in regard to international congresses in archæology, it was desirable that the prehistoric section of the Congress of Archæology should be enlarged It then appeared that there was a desire for a quite new organisation Since 1929, however, there has been a fundamental change in the situation The attempt made by the Institut international d'Anthropologie of Paris to revive, and at the same time absorb into its own machinery, the old pre-War Congrès d'Anthropologie et Archéologie préhistorique, by issuing a joint invitation to the congress at Lisbon in 1930, would appear to have strengthened the dissatisfaction of archæologists with the present position rather than have reconciled them to a congress which, while international in name, is attached to a permanent organisation, bound under French law to be predominantly French in composition As a result of inquiry, it would appear from a report published by Prof J Myres in the April issue of *Man*, there is a widespread agreement among archæologists of all nationalities, including even some French, that future congresses should be entirely separated from the Paris Institut and, in fact, that the old Congrès should be revived in accordance with its former statutes

PROF MYRES goes on to forecast the probable lines of discussion at Bern in the light of consultations and correspondence with Continental archæologists The questions to be settled will be whether international organisation in the future should provide for a single congress to cover all human sciences, anthropology, ethnology, technology, as well as prehistoric archæology, or should (at any rate at present) a congress be organised to deal with prehistoric archæology only, and, secondly, whether an entirely new congress on fresh principles should be organised, or should the pre War Congrès d'Anthropologie et Archéologie préhistorique be revived by friendly agreement with the surviving representatives of the old Congres and the Paris Institut as an entirely independent institution On these points the attitude of British archæologists is set out in a series of resolutions passed at a recent meeting of the Joint Committee on Teaching and Research of the Royal Anthropological Institute a fully representative body In these, the desire is expressed that the Congrès should remain in being as an independent body, and the Committee conveys to the meeting at Bern the hope that any future congress for prehistoric archæology will admit the more general studies of anthropology and ethnology, which illustrate all the various aspects of prehistoric archæology

UNDER the auspices of the Museums Association and the Carnegie United Kingdom Trust, an exhibition of

museum specimens specially prepared for circulation to rural areas was held in the County Hall, Westminster, on Jan 28–30 The exhibition aimed at showing, for the information of museum curators, educationists, and the public generally, what can be done and what is being done to extend the influence of museums to country schools and to the people Nine provincial museums, the Canadian Commission, and three United States museums sent exhibits, which represented very fairly the possibilities of this branch of service, as well as the limitations imposed upon it by difficulties of size and transportability It is very gratifying to know how greatly this museum work is appreciated in the districts where it prevails The *Museums Journal* for March associates with an account of the exhibition, photographs of some of the series shown One of the great difficulties of curators is to obtain, at reasonable cost, cases at once suitable for exhibiting specimens (often of considerable depth) and for bearing the strains of travel by rail or carrier May we suggest that the Museums Association would play a most useful part were it to arrange for the mass production of a standard transportable case, probably after the type used by the American Museum of Natural History, which, to us, seems best to meet requirements

A list of the industrial research laboratories of the United States of America has recently been published as *Bulletin* No 81 of the National Research Council (Publication Office, National Research Council, Washington, D C No price) It is the fourth edition of this bulletin and shows a great increase, in the number of industrial research centres listed, on the third edition of 1927 The increase in number is about 60 per cent and may be indicative of either the great progress of industrial research in the United States or a greater interest of such research laboratories in this compilation by returning data for publication, or both The list is of industrial laboratories only and does not include, therefore, laboratories connected with the Federal, State, or municipal governments, or with educational institutions Since, as the compilers of this bulletin admit, such laboratories often do attack problems of industrial importance, it seems a pity that they were not included These laboratories usually are listed in other publications, yet their inclusion probably would have added to the value of this bulletin, by making it even more comprehensive The data given under each laboratory were furnished by the director of the laboratory, in reply to a questionnaire, of which the chief parts apparently were name and address of the company (under which the laboratory is listed), director and research staff, account of research work, and, in a few cases, development work Following this list of industrial companies' laboratories, is an alphabetical list of directors and their addresses Then comes the geographical distribution of the laboratories, grouped into towns and States Finally, there is an alphabetical grouping of the subject matter of research The last two lists form indexes to the whole volume, thus making reference comparatively easy So far as we know, there is no similar list of industrial research laboratories in Great Britain, such a list should prove of great value as a reference guide to all types of research workers

It is announced that the Whipsnade Zoological Park will be opened to the public on Saturday May 23 The park will be open every day afterwards, including Sundays from 10 A M until lighting up time

A small earthquake was recorded at Kew Observatory at 17 hr 3 min 9 sec G M T on April 15 It is estimated that the disturbance originated 1300 miles away, the epicentre being under the Atlantic to the north of the Azores

The Faraday Medal (tenth award) will be presented to Mr Charles H Merz at the ordinary meeting of the Institution of Electrical Engineers to be held on Thursday, April 30 The presentation will precede the twenty second Kelvin Lecture, which will be delivered by Prof W L Bragg on "The Architecture of Solids"

The annual visit to the Research Station, Long Ashton, Bristol, will take place on May 7, when the ciders made during the season 1930–31 will be displayed and the fruit plantations of the Station will be open to visitors from 11 A M to 4 P M Demonstrations of small horticultural machines and implements, including cultivators, spraying and dusting machines, etc, will be in progress throughout the day

The Pontifical Academy of Sciences (Nuovi Lincei) is offering a prize of 10,000 lire for a critical dissertation on the law of Mendel and the chromosome theory Essays must be unpublished and may be written in English, French, German, Spanish, Italian, or Latin They may be signed or written under a pseudonym, and must reach the Pontifical Academy of Sciences, The Vatican City, before Oct 30 The award will be announced at the first meeting of the Academy in December

The work of the National Physical Laboratory is illustrated by a series of transparencies now on view in the entrance hall of the Science Museum, South Kensington They include illustrations of a radium safe, one million volt spark, internal view of the high voltage laboratory, and the primary standard barometer There is also an exhibition illustrating the occurrence of earthquakes and instruments used in their measurement, with the records obtained at Kew from a number of recent earthquakes Both series of exhibits will be on view until the end of June

The Linnean Medal for 1931 of the Linnean Society of London has been awarded to Prof Karl E von Goebel, professor of botany in the University and Director of the Botanical Gardens, Munich The following have been proposed as foreign members of the Society Prof Carl Christiansen, of Copenhagen, Dr K E Correns, Director of the Kaiser Wilhelm Institute of Biology, Berlin, Dr L Diels, Director of the Botanical Gardens, Berlin, and Prof F A F C Went, professor of general botany in the University of Utrecht

Sir James Jeans left England on April 18 for the United States, primarily to receive the Franklin Medal

from the Franklin Institute, Philadelphia On May 18 Sir James will deliver a lecture in Washington under the auspices of the Carnegie Institution He will visit the Bartol laboratories in Philadelphia on May 19, and on May 20 will receive the Medal from the Franklin Institute and there deliver his lecture This will be followed by three lectures, at Princeton (May 23), Harvard (May 25 or 26), and Yale (May 26 or 27), which are being given under the auspices of the Franklin Institute Sir James will sail for England towards the end of May

THE preliminary programme of the forty second congress of the Royal Sanitary Institute, which will take place at Glasgow on July 4 11, has recently been issued Sir Henry Mechan will preside over the congress, which will be divided into the following sections preventive medicine, architecture and engineering, maternity, child welfare, and school hygiene, hygiene of food, hygiene in industry, veterinary hygiene and national health insurance Five conferences have also been arranged, of sanitary authorities, medical officers of health, engineers and surveyors, sanitary inspectors, and health visitors The inaugural address will be given by Sir Henry Mechan, and the congress will terminate with a lecture by Major Walter Elliot on "A Continuous Health Policy" A health exhibition in connexion with the congress is projected, and there will be opportunities for visits to hospitals and other institutions and places of local interest

THE preliminary programme of the Second International Congress of the History of Science and Technology is now being sent out, and we note that it is intended as the subject matter of the Congress is so extensive, that members should speak to three general themes namely (1) The sciences as an integral part of general historical study, (2) Historical and contemporary inter relationship of the physical and biological sciences, (3) Inter dependence of pure and applied science For the afternoons and evenings, visits have been arranged among other places, to the Royal Society, Royal Institution, Royal Observatory (Greenwich), National Museums, Institute of Historical Research and Down House Kent There will also be excursions to Oxford and Cambridge Most satisfactory responses have already been made and the Congress bids fair to be a very great success Further particulars will be furnished upon request by the honorary secretary of the Congress, The Science Museum, South Kensington, S W 7

WITH reference to the article on medals awarded for scientific achievement, published as a supplement to NATURE of Nov 15, 1930, and the additional list in NATURE of Mar 7, our attention has been directed to a further medal award In 1928 the Bombay Branch of the Royal Asiatic Society established a silver medal, to be given triennially to a member considered to have made the most signal contribution in Oriental scholarship during the previous three years The first medal will be presented this year to Mr S V Karandikar, for his book "Hindu Exogamy A Systematic Study of Hindu Marriage Outside the Gotra" This book was noticed in NATURE of Mar 15, 1930

WITH the December number, 1930, the *Tropical Veterinary Bulletin* ceased publication, and in its place the Imperial Bureau of Animal Health is publishing a new journal under the title of the *Veterinary Bulletin* This includes the matter of the *Tropical Veterinary Bulletin* and, in addition, the diseases of temperate climates The first volume of about 384 pages is being issued in four quarterly parts, commencing April 1 but from January 1932 the journal will be published monthly, and the volume will run to about 600 pages The subscription price is £1, post free which should be sent to the Imperial Bureau of Animal Health, Veterinary Laboratory, Ministry of Agriculture and Fisheries, Weybridge, Surrey, England

A USEFUL classified catalogue of new and second-hand books on medical subjects has just been issued by Messrs W and G Foyle, Ltd, 119 Charing Cross Road, W C 2 It can be had free of charge upon application

WE have received a volume of collected reprints of "Researches published from the Wards and Laboratories of the London Hospital during 1930" It is edited by Mr Hugh Cairns, and contains 39 papers dealing with a variety of subjects—clinical medicine and surgery radiology, pathology bacteriology, and physiology Five papers deal with psittacosis or parrot fever The paper by Bedson and Western shows that the virus is a filterable one, though probably of relatively large size and that the guinea pig is susceptible to the virus and may be employed for maintaining strains

A CATALOGUE (No 456) of nearly 1300 second hand books of science has just been received from Messrs Bowes and Bowes, 1 Trinity Street, Cambridge The subjects are arranged under the headings of journals (general) agriculture anthropology and ethnology, biography and travel, biology (with microscopy, evolution, and heredity), botany (with a small collection of herbals) chemistry and physics, entomology (with arachnida, and crustacea) forestry and gardening, mineralogy and geology mollusca, ornithology, zoology (general with parasitology), and addenda (all subjects) The prices asked appear very reasonable

APPLICATIONS are invited for the following appointments, on or before the dates mentioned A head of the senior engineering department of the Hull Municipal Technical College—The Director of Education, Education Offices Guildhall, Hull (May 2) A senior lecturer in electrical engineering and an assistant lecturer in marine engineering at the Liverpool Central Municipal Technical School The Director of Education, Education Office, 14 Sir Thomas Street, Liverpool (May 2) A lecturer in mathematics with subsidiary physics and a lecturer in building technology and science at the Rugby College of Technology and Arts—The Principal

and Organiser of Further Education in Rugby, 61 Clifton Road, Rugby (May 8) An assistant in the chemistry department of the Coventry Municipal Technical College- The Director of Education, Council House Coventry (May 22) A professor of anatomy in the University of Birmingham—The Secretary, The University, Birmingham (May 30) A university student in physiology in the University of London- The Academic Registrar, University of London, South Kensington, S W 7 (May 31) A temporary lecturer in chemistry at the Huguenot University College, Wellington, Cape of Good Hope— Miss M S H Kilroe, St Paul's Girls' School, Brook Green W 6

Our Astronomical Column

Comets —*Pop Astr* for April contains photographs of comet Schwassmann Wachmann before and after the recent outburst reported in NATURE for April 11 They were taken by Prof G van Biesbroeck with the 24 inch reflector at Yerkes Observatory The first was taken on Dec 16 1930 when the comet's magnitude was about 16 in spite of its faintness Dr F E Ross has managed to bring out an appreciable amount of coma by making successive photographic copies The second photograph taken on Feb 11 1931, shows the comet as a small bright disc of magnitude 12 5 Examination of the original negative showed a little diffused light at the edge of the disc, but the extended coma had vanished By Mar 10 the comet had again sunk to magnitude 16 and the outer coma was again visible On Feb 11 the comet was 7 05 units from the sun 6 33 from the earth Prof van Biesbroeck is confident that it will remain visible round the whole of its orbit which will be a new cometary record It is now within two years of aphelion passage

Dr K Reinmuth of Konigstuhl Observatory, announces in *Astr Nach* 5779 that he has detected images of a comet on plates taken in March 1902 It was 1 5 in diameter with a faint nucleus and a short tail in P A 220 , magnitude 12 0 He suspects that it may be a periodic comet but it has not been identified with any known one The positions are given in the hope that other images may be found on old plates

The aphelion is about a unit inside the orbit of Jupiter, so the perturbations will be considerable The magnitude is 13

Parallaxes of Stars at different Galactic Latitudes —*Publication* No 45 of the Groningen Laboratory has a paper on this subject by Dr P J van Rhijn and B J Bok Its object is a re determination of the mean secular parallaxes of stars of various magnitudes grouped with reference to their galactic latitudes It is concluded that the distances of the faint stars in high galactic latitudes were over estimated in the similar research in *Publication* No 29 The proper motions have been re investigated, using all the recently published star catalogues and some special investigations for faint stars by Alden, P van de Kamp, and A van Maanen The effects of galactic rotation have been taken into account, using Oort's formulæ of correction

The following is a summary of the resulting mean secular parallaxes

Mag	Lat 0 to 40	Lat 40 to 90
7 0	0 033″	0 047″
9 0	0 017″	0 027″
11 0	0 0086″	0 015″
13 0	0 0045″	0 009″

Tables are given to facilitate the deduction of absolute proper motions of faint stars from their relative values as derived from photographs They include the effect of differential galactic rotation

The Distant Faint Companion of Castor *Bull Astr Inst Netherlands* 6, No 216, contains a full study of this faint star which belongs to the system of Castor, and is, like the two bright components, a close binary , it is also an eclipsing variable The two stars composing it appear to be practically identical in size and brightness, each of them is 432,000 km in radius, and of mass 0 593 sun, density 2 468 sun surface brightness 3 45 magnitudes darker than the sun, total brightness 4 48 magnitudes fainter than the sun Adopting 5741° as the sun's effective temperature, that of Castor *C* is found to be 3400°, in good agreement with its type of spectrum, which is *M* Its colour index is 1 52 magnitude The orbit appears to be circular , the full period of revolution (that is, double the period of light variation) is 0 8142822 day, and the radius of the relative orbit 2 701 000 km The absolute visual magnitude of each component is 9 15 magnitudes It is noted that the masses and magnitudes accord well with Eddington's mass luminosity relation

The Distances of the Cepheid Variables —A recent note in this column described B P Gerasimovic's researches on this subject leading to the conclusion that Prof Shapley's absolute magnitudes needed to be corrected by +1 0 mag , and his distances reduced in the ratio 0 631 to 1 *Astr Nach* 5775 contains a research on the same subject by A Kipper It makes use, in addition to proper motions and radial velocities, of the fact that the angular radius of a star of known colour index can be deduced from its apparent magnitude By applying this to different stages of the Cepheid variation, the change of angular radius can be correlated with the radial velocity. From a combination of all the methods he finds +1 1 as the correction to Shapley's absolute magnitudes This is so close to the 1 0 of Gerasimovic that it gives ground for receiving both results with some confidence

Research Items

A Neolithic Statuette from Malta.—Sir T. Zammit figures and describes in the *Bulletin* of the Malta Museum, vol. 1, No. 2, a fragment of a stone statuette found in 1929 in clearing the exterior of the apses of the Tarxien neolithic temples. What is left of the statuette shows details lacking in other statuettes from the megalithic ruins. It is 30 cm. high and has a width of 21 cm. with a flat base 10 cm. by 7.5 cm. The upper part, corresponding to the waist, has a hollow, carefully worked, which served as a mortice for the insertion of a dowel to bear the upper portion. The figure is draped with a flounced short skirt, and is sitting or leaning on a bench. A pear-shaped leg protrudes beyond the skirt. Each pair of pleats of the skirt is surmounted by a semicircular embroidered line forming a continuous decoration. The hips are prominent. The bench on which the figure sits ends in a horizontal frame supported by standing human figures in high relief, the heads appearing as decorative knobs under the frame. They stand in typical hieratic attitude with the left forearm bent across the breast, the right arm hanging loosely by the side. The figures wear a plain tunic falling in folds to the ankles to conceal the feet. Another figure in bolder relief is seated at right angles to the three figures, its arms folded and its hands resting on the obese thighs. These carved figures are peculiar to Malta.

A New Species of *Ornithobilharzia*.—R. Wetzel (*Proc. U.S. Nat. Mus.*, vol. 78, art. 3, 1930) describes a new species of the trematode genus *Ornithobilharzia* from a Canadian goose from Virginia. The description is based on three males and three females found in branches of the portal and mesenteric veins. The testes in the male are 28 in number, that is, fewer than in other species, and the females are longer than the males (about 9 mm. and 6 mm. respectively). Eggs collected from the intestinal contents of the goose are oval, provided with a small terminal spine, and contain active miracidia. The author gives a detailed description of the anatomical characters of the male and female, and a key to the known species of the genus *Ornithobilharzia*.

Researches on Earthworms.—In vol. 5, No. 3, of the *Science Reports* of Tohoku Imperial University, 1930, there are several papers dealing with researches on various oligochætes of Japan. Some of these worms are very large and lend themselves readily to experiment. *Pheretima* is a favourite genus for the purpose. In the first paper, "On the Body Temperature of the Earthworm", by Hojik Kim, *Pheretima megascolidioides* is used, the purpose of the work being to determine the ability of the adjustment of body temperature within a wide temperature range. These worms quickly adjust themselves to the surrounding medium within the temperature range of from 6° to 23° C., beyond which the ability to regulate steadily decreases as the temperature rises. Three species of *Pheretima* and one of *Allolobophora* were used by Du Hyen Zyeng for his work on the "Distribution of the Intermuscular Nerve Cells in the Earthworm". It is suggested that these cells are vestiges of the primitive nerve net of lower invertebrates. Ekitaro Nomura and Shinryo Ohfuchi continue their work on "The Effect of Inorganic Salts on Photic Orientation in *Allolobophora fœtida*. 5, Sodium Salts—Na_2SO_4, $NaNO_3$ and $NaCl$", and Shinkishi Hatai describes a large new semi-aquatic oligochæte which he names *Drawida hattamimizu*. This is said to have been known for years to the people living in the villages near Kahoku Lake, opening into the Japanese Sea, and is used extensively by the local fishermen as a live bait for eel fishing, the specific name being their local name for it. The largest seen measured more than three feet in length when crawling, although the posterior part was not fully extended. It is an interesting fact that this huge worm made its appearance suddenly in the locality mentioned, and Dr. Hatai thinks it was probably imported—perhaps by the celebrated merchant and explorer Gohei Zeniya, who was born in Hatta village, where the worm is specially abundant. So far it has not been found in other localities, although it is suggested that its original home is very likely to be in the Philippine Islands or in Java, which Gohei Zeniya is supposed to have visited in his travels. Minoru Oishi, "On the Reproductive Process of the Earthworm *Pheretima communissima* (Goto et Hatai), Part 1", records some very interesting observations on the mating of these worms.

Lipin of *Hevea* Latex.—E. Rhodes and R. C. Bishop (*Quarterly Journal of the Rubber Research Institute of Malaya*, vol. 2, No. 3, 125-135) have isolated from fresh latex a complex lipin-like substance which exists in the latex in quantities of the order of 0.2 per cent. It was obtained as a solid waxy body by laborious treatment of fresh samples of the latex with rectified spirit, concentration under reduced pressure, and subsequent ether extraction. The substance disperses in water, reduces the water-air surface tension, and the very stable aqueous suspension is coagulated by acids at pH 1.9 to 2. The method of preparation, general chemical properties, and the products obtained by hydrolysis clearly indicate that the substance obtained was a lipin but of quite complex and not entirely elucidated structure. Different samples have constant N : P ratio (1 : 1.31) and 95 per cent of the fatty acids, which constitute 70 per cent of the total weight of the substance, are liquid and have iodine number 123. Like some other similar bodies from plants, it contains a large amount of carbohydrate (10 per cent) which was only removed by somewhat drastic hydrolysis. Apparently the sugar is not present as reducing sugar, though reducing properties are quite evident after acid hydrolysis, when an osazone may be prepared. Though the presence of glycerol has not been definitely established nor the particular nitrogen base or bases identified, it is interesting to note that calculations of the phosphorus as glycerophosphoric acid, the nitrogen as choline, the sugar as hexose, together with the fatty acids, unsaponifiable material and ash, enable a complete account to be made of the original material. This lipin complex has also a technological claim to examination since Messrs. B. J. Eaton, E. Rhodes, and R. C. Bishop (*ibid.*, pp. 136-138) have shown that it has an accelerating effect on the rate of vulcanisation.

Embryology of *Sargassum*.—Until recently, comparatively little has been known of the details of embryology of the Fucales apart from a few of the northern hemisphere genera, such as *Fucus* and *Pelvetia*. The studies on a number of sub-tropical genera and species by the Japanese school of botanists should help towards a more definite classification within the group and especially in the sub-group of the Cystosiro-Sargasseæ, which is well represented on that coast. Inoh's paper on "Embryological Studies in Sargassum" (*Science Reports* of the Tôhoku Imperial University, vol. 5, No. 3) shows that the species examined—12 out of the 41 in Yendo's monograph—fall into three groups, each of which is characterised by the method of segmentation of the primary rhizoid cell and the number of rhizoids produced on the embryo. At first sight, this appears a somewhat detailed point on which to base a comparison

of species, but so far as it has been investigated, the embryology, which is also associated with the size of the egg, appears to be very constant and also to be associated with definite features of the subsequent habit of the plant If further investigation confirms the constancy of certain types of embryo development, this should prove to be a useful method in deciding affinities of doubtful species A case in point is that of *Turbinaria* (?) *fusiformis*, which some algologists have suggested should be placed under *Sargassum* This suggestion receives support from embryology, as the details described by Tahara for the segmentation of the rhizoidal cell and number of rhizoids agree with the details given by Inoh for a group of *Sargassum* species which are characterised by the irregular division of the primary rhizoidal cell into eight cells, each of which grows out into a rhizoid

Sugar Beet Varieties —Among the reports published in vol 2, No 4, of the *Journal* of the National Institute of Agricultural Botany, that which deals with the sugar beet variety trials during 1927-29 is of particular topical interest The tests have been carried out with replicated plots at several centres simultaneously and have been repeated successively, all results receiving statistical treatment The types of sugar beet fall into three main groups (1) class *E*, which is high yielding, but with average or less than average sugar content, (2) class *Z*, with a high sugar content, but with yield below the average, (3) class *N*, which consists of varieties intermediate between *E* and *Z* The report deals with strains of the *E* type, Dippe *E* being selected as a standard for comparison From the point of view of yield, Kleinwanzleben *E* proved the best variety, Dippe *E* and Hoerning *H S* taking the second and third places respectively As regards sugar content, however, these three strains were poorer than any other, yet on a basis of yield of sugar per acre, they again headed the list Further, Kleinwanzleben *E* and Dippe *E* proved the most profitable when their cash value per acre was determined, a figure calculated from yield sugar content, and factory price In estimating the value of sugar beet crops the yield of tops must not be overlooked, but on this point also these varieties proved satisfactory As regards non bolting tendencies however, Kleinwanzleben *E* was slightly the superior For general purposes therefore, Kleinwanzleben *E* and Dippe *E* are recommended as the most suitable for growing under English conditions, but on rich black soils, Marsters or Kuhn *P*, both small topped and non bolting strains, are considered preferable, for the danger of excessive leaf development is avoided, and they may be sown very early with safety

The Proposed Madden Reservoir (Panama Canal) —The necessity of a large supply of water for lockages in the Panama Canal has engaged the attention of the engineers in charge for many years In recent years it has become increasingly evident that more water than is now available in Gatun Lake during the dry season must be provided to meet future requirements Consequently studies have been made of the feasibility of a storage reservoir on the upper Rio Chagres which would conserve the flood waters for use in the dry season, allow the development of additional hydro electric power, and aid in the prevention of dangerous currents such as occur in the Canal near Gamboa during floods The geological investigation has been made by F Reeves and C P Ross, and their conclusions and recommendations are published in *Bull* 821 B of the U S Geol Surv, 1931 (pp 49 and maps) The rocks are calcareous and tuffaceous sedimentary rocks of Tertiary age, resting on a volcanic complex of probable Eocene age They are bent into a structural basin that corresponds approximately with the topographic depression in which the reservoir would be formed The structure is such as to assure that any leakage would find its way into Gatun Lake, as desired Some of the rocks are thus permeable to water and others are mechanically weak, but despite these disadvantages the project is found to be feasible

Glacial Geology of Connecticut —Prof R F Flint, of Yale, has recently completed the first systematic study of the glacial features of Connecticut as a whole, and the results have been published in *Conn Geol and Nat Hist Survey, Bull* 47 (Hartford, 1930, pp 294) It is concluded that after the last invasion of the ice had reached its greatest extent, with its front lying along or south of Long Island, it passed into a 'dead' or stagnant state Once its power to move had gone the blanket of ice must have melted away from the surface downwards As more and more of the previously buried highland surface emerged, the ice was gradually left only in the valleys The melt-water made its way seawards through narrow channels left between the ice and the valley sides Terraces are left representing the marginal lakes of successively lower levels, the lakes having been filled up delta wise by deposits that were banked up against the ice margin The faces of the terraces are faithful casts of the irregular margins of the stagnant ice, and their surfaces are pitted with kettle holes representing isolated slabs of ice that were buried and afterwards melted out It is noteworthy that the terraces do not slope southwards with the stream gradients, but are quite horizontal This indicates that the differential tilting that uplifted the regions to the north did not affect Connecticut

Compensation of Ship's Direction Finders —In the early days of building iron ships, one of the greatest difficulties in the way of navigating them was to eliminate the effects of the ship's magnetism on the mariner's compass The most important effect is the 'semicircular' error, due mainly to the permanent magnetism of the iron girders, beams, and steel masts of the ship Another effect is the quadrantal error due to induced magnetism The first effect is corrected by placing two steel magnets in a certain position, and the second by two soft iron spheres placed one on each side of the compass In a paper on radio direction finders read by C E Horton to the Institution of Electrical Engineers on Mar 4, the methods of correcting their errors are discussed It is pointed out that these direction finders, like the mariner's compass, are affected by both semicircular and quadrantal errors The effects produced by the currents which flow in conducting paths in the ship have to be corrected by a loop suitably oriented and placed near the direction finder It has also to be shielded from the effects of the displacement currents in the dielectric by a subsidiary aerial coupled inductively to the direction finder This latter effect is corrected either by a fixed aerial system (Bellini Tosi) or a rotating coil system The semicircular error is due to the fact that although a ship is symmetrical about a central longitudinal line, it is not symmetrical about a transverse line The best position for the finder is as high above the hull as possible In some ships it is possible to put the coil on the top of the mast and above the level of other aerials In this position excellent results are obtained Whenever a blurred zero is obtained, it indicates the presence of a downcoming or atmospheric ray, and in this case the error of the apparent bearing may be large

Discharge through Sluices—Physical Department Paper No 25, issued by the Ministry of Public Works, Egypt, describes the experiments made under the direction of Dr H E Hurst, on three models of the sluices fitted in the Aswan Dam and Sennar Dam of the Nile Two of the models were to a scale of 1/50, and the other to a scale of 1/25 The experiments were made either at the School of Engineering, Giza, or at the Delta Barrage, while the total number of discharges measured during the work described in the paper was about 3700 Experiments were made under three conditions of flow free conditions, submerged conditions, and intermediate conditions, and the conclusion given is that the results show that the usual theory given in the textbooks on hydraulics is inapplicable, and that the flow through a sluice and culvert is complicated It can be described simply only when the flow is free or submerged, but not when the regime is intermediate between these

New Raman Effect Apparatus—The December issue of the *Indian Journal of Physics* contains a paper by Prof B Venkateschar and L Sibaiya, of the Central College, Bangalore, in which they describe a new apparatus for the study of the Raman effect in solids, liquids, and gases and mention some of the results they have obtained with it The material to be tested is enclosed in a short length of silica tube and placed at the centre of a long silica tube of 2 cm diameter, which is surrounded by a glass tube of 3 cm diameter The glass tube has a short tube projecting downwards filled with mercury, which serves as the cathode A bulb of about 5 cm diameter projects upwards from the long glass tube and has, at its centre, the tungsten anode When the mercury arc is formed, the part of the silica tube containing the specimen is entirely surrounded by it and the effect of the mercury line 2536 in the ultra violet may be observed By passing air at temperatures between 120° C and 400° C, through the silica tube, the effect of temperature on the Raman lines has been investigated for calcite, aragonite, and acetylene As would be expected, the lines become more diffuse with rise of temperature

Optical Properties of Mercury Solutions—A neat demonstration of the fact that mercury is soluble in water, methyl alcohol, and hexane is afforded by an investigation of the absorption of ultra violet light by such solutions, of which an account is given by K F Bonhoeffer and H Reichardt in the *Zeitschrift für Physik* for Feb 25 The absorption spectrum consists, in each case, of a pair of diffuse bands near the mercury resonance wave length (λ2537) The centres of the bands, if regarded as associated with λ2537, are displaced towards the red, but when the density of the liquid is reduced by superheating, the bands close in on each other and approach the resonance line The explanation offered of these observations is that the bands represent Stark components of the resonance line, the active electric fields being those of neighbouring molecules of the solvent, but it is difficult to account quantitatively for the magnitude of the effect. In the aqueous solution there is further absorption at about 2200 A, which has been tentatively ascribed to ionisation of the mercury

Conductivity Cells—In 1923 H C Parker published two papers which challenged a fundamental postulate of the Kohlrausch method for the measurement of the conductivity of electrolytes by the observation that the cell constant of a particular cell appears to vary with the resistance being measured The observation was confirmed by Randall and Scott in 1927, and some difficulty was experienced in accounting for it In the February number of the *Journal of the American Chemical Society*, Jones and Bollinger have examined the problem, and they show that the effect is caused by the use of the pipette form of conductivity cell, which has recently been much used by American workers and considered to have advantages over the older types of cell They show, both by calculations and experiments that with cells of this type there is a capacitative shunt between parts of the cell of opposite polarity, which has the effect of making the measured resistance lower than the true resistance of the electrolyte between the electrodes They also show that, whereas earlier experimenters have reported a variation in conductivity of electrolytes with change in frequency, no such change can be detected between the limits of 1090 and 4000 cycles per second, when the errors due to polarisation and capacitative shunt are avoided The design of the conductivity cell has been modified, and the resulting cells, which are very similar to the older types previously used, are said to be capable of giving very accurate results The ratio of the resistances of a pair of cells when filled with a common solution was found to be independent of the electrolyte used for three different electrolytes The peculiar effects which have been published in recent years would thus appear to have been due to experimental errors

Transition Temperature of Glauber Salt—The temperature at which the transition

$$Na_2SO_4, 10H_2O \longrightarrow Na_2SO_4 + \text{satd solution}$$

occurs has been measured by several methods by Oguri and co workers, the results being given in the *Memoirs* of the Faculty of Science and Engineering, Waseda University, Tokyo, No 7, 1930 The values are 32 46° (viscosity), 32 367° (dilatometer), 32 302° (solubility), 32 57° (static vapour pressure) and 32 57° (dynamic vapour pressure) The account of the dilatometric experiments includes a mathematical theory of the determination, in which it is shown how a more accurate value may be obtained from the results than by the usual simple graphical method

Silicic Acid Hydrosol—The preparation and properties of hydrosols of silicic acid are described in two papers by K Inaba in *Scientific Papers* of the Institute of Physical and Chemical Research Tokyo, Nos 278 279, for December The sols, prepared by the hydrolysis of ethyl silicate in presence of small quantities of inorganic acids and of alkalis respectively, showed differences in their properties The 'acidic sol' prepared in presence of acids could not be completely purified by electrodialysis, as it began to coagulate when the acid concentration was reduced to about 0 0002 *N*, whilst that prepared in presence of alkali could be perfectly freed from alkali by electrodialysis without causing coagulation, and is called the 'neutral sol' The acidic sol showed rather less conductivity and greater viscosity than the neutral sol Velocities of migration in an electric field were determined for those sols and for those prepared from silicon tetrachloride by hydrolysis and from sodium metasilicate and hydrochloric acid Acidic sols had a small degree of dispersion, small migration velocity and particle charge, whilst neutral sols had a great degree of dispersion and migration velocity The viscosity minimum produced on addition of electrolyte was situated in the neighbourhood of the isoelectric point The author is of the opinion that the peptising action of the chloride ion is important for stability, as well as hydration or charge, and is most powerful at the isoelectric point

The Royal Polytechnic Society, Cornwall

Amongst the oldest of provincial societies the Royal Cornwall Polytechnic Society which has its headquarters at Falmouth is one of those which has adapted itself to the changing times and continues to serve the interests of Cornwall in many ways. Instituted nearly a century ago for the sole purpose of holding exhibitions to encourage workmen and students and to give them the opportunity of showing their work, the annual exhibition and the summer meeting held simultaneously continue one of the Society's main activities. The scope of the exhibition held in July 1930 at Penzance is especially referred to in the ninety-seventh Annual Report of the Society, which records that the exhibition was visited by more than 6000 persons.

The Report also refers to the work of the Falmouth Meteorological Observatory, the Cornwall Rainfall Association with more than fifty observers in the county, and gives reports of the papers read at the summer meeting and some interesting biographical notes. Among these is a sketch of the career of the president, Dr. J. H. Rowe, of Bradford. Born in Hayle in 1870, Dr. Rowe graduated in medicine at Aberdeen and in 1899 began to practise in Bradford, where he has held the presidencies of the Bradford Literary Club, the Bradford Scientific Association, and the Bradford Historical and Antiquarian Society. He is, however, as well known in Cornwall as in Yorkshire, and possesses a unique collection of books, pamphlets, portraits, and documents relating to Cornwall, and his presidential address of last year to the Polytechnic Society was a review of the work of Cornish inventors.

In this address Dr. Rowe said that from a study of the records of some 350 inventors of Cornwall who previous to the year 1890 had invented objects of use or had taken out patents, he could not help drawing the reasonable inference that Cornwall in the past had had more than the average share of clever men. Among those to whom he referred more particularly were Robert Were Fox, inventor of the dipping needle; Davy, whose safety lamp had been the means of preventing countless accidents; Trengrouse, inventor of the unsinkable lifeboat, the cork jacket, and the rocket life-saving apparatus, who spent his fortune of £3500 on his inventions and died a poor man; Loam, inventor of the man-engine for raising miners from great depths; Trevithick, whose work was "brilliant, meteoric, sensational, but nevertheless effective"; Woolf, improver of the steam engine; Husband, whose pneumatic stamper for crushing minerals was first tried at Hayle Foundry in 1870; the Hornblowers, whose work is dealt with in a separate paper by Mr. R. Jenkins; Gurney, who invented the Bude Light and built steam carriages; the Tangye brothers; Roseveare, who in 1889 made the first wrist watch; and William Christophers, pattern maker of Hayle, who is said to have invented the spliced cricket bat and to have shown it to Lillywhite, through whom the invention became universally adopted.

Two of the papers included in the Report deal with Cornish copper and tin mining. The first, on "Tributers: their Uses and Abuses", is by Mr. A. K. H. Jenkin, and the second, on "Abandoned Cornish Mines", is by Mr. E. W. Newton, the secretary of the Society. A tributer is a miner who, in lieu of an ordinary weekly or monthly wage, agrees to work for a percentage of the total value of the ores he sends to the surface after paying the cost of all the tools and materials necessary for winning the same. The tributary system is of great antiquity and if tributers were properly encouraged they might continue even yet to stimulate Cornish mining. If recognition of their work is not made now, however, another decade or so and the race of men capable of rendering such services will have gone.

Mr. Newton's paper deals with the history of the Gwennap mines, which once employed many thousands of miners and from which many fortunes were made. The ores consisted of minerals rich in copper, such as native copper, oxides, arsenates, and grey sulphides. Connected with the Gwennap mines was the great County adit, begun nearly 170 years ago, "the finest and most extensive mining engineering feat carried out in Cornwall". Of the value of the mines Mr. Newton gives many particulars. South Wheal Jewel distributed £400,000 in profits in ten years; Wheal Virgin in 1757 produced copper ores in five weeks which sold for £15,000, at a working expense of £200; in 1806 Wheal Damsel was making a profit of £36,000 a year. The most fascinating mining adventure was the Wherry Mine, the shaft of which was off the coast near Penzance, 700 feet beyond high water mark. The tin ore was very rich, and it is said, "1 cwt. of white tin was obtained from a sack of ore". An American vessel breaking loose from her moorings demolished the works and the mine came to an end.

Crabs and Lobsters on the Coasts of Britain

An Interdepartmental Committee appointed by the Minister of Agriculture and Fisheries and the Secretary of State for Scotland to inquire into the Crab and Lobster Fisheries was set up in 1925 to examine the present position of crab and lobster protection in Great Britain. Its report, which has recently been published (London: H.M. Stationery Office, 1930, 1*s.* 6*d.* net), is based on statistics of landings and information as to the catching power employed in these fisheries. The scope of the inquiry was restricted to the eastern and southern coasts of England and the western coast south of the Bristol Channel and the Isle of Man. The Committee had also under consideration information as to the state of the fishing in various localities in England, and from the fishery districts in Scotland with local reports on the crab fisheries in 1923. These constitute a valuable basis for comparison with further data, taken together with landing statistics. It is recommended that similar inquiries into the catching power employed be held in 1932.

Investigations were undertaken by the Fisheries Department of the Ministry of Agriculture and Fisheries, with the co-operation of the local fisheries committees of England and Wales, to collect data with regard to size, sex, and condition of crabs. The object was to obtain definite information as to the immediate proportional loss which would result in various districts as a consequence of the introduction of measures intended to give further protection, such as increasing the minimum size at which crabs may be legally taken, prohibiting the use of undersized and soft crabs for bait, or the imposition of a close season where there is not one at the present time. After careful consideration, it was decided not to recommend the introduction of further statutory protective measures in respect of the crab fishery, as there is no falling off in the yields compared with

those of the pre-War years 1911–1913, but rather an upward tendency in the catches during more recent years. It was felt that an increase in the general size limit would entail an immediate loss of a serious nature to a section of the fishermen. As to the destruction of soft crabs, conditions are so different that if more legislation were necessary, close seasons would be different for different areas. It is, moreover, in the power of local fisheries committees to make bye-laws imposing further restrictions on the taking of crabs.

It is recommended that further inquiry into the migratory movements of the crab be pursued and special attention is directed to the experiments on the growth of the lobster at present being carried on at the Scottish Marine Biological Station at Millport. It is anticipated that much light on the life-history of the lobster will result from this work.

Appendices containing the various statistics, with bibliographies of literature relating to crabs and lobsters, are included in the report.

The Law and Practice of Treasure-Trove

THE law of treasure trove has been so ill defined in the minds of most working archæologists that we welcome the announcement made in the *Museum Journal* for April to the effect that negotiations on the subject which have been in progress for several years between H.M. Treasury and the British Museum have been brought to a satisfactory conclusion. The decisions of the negotiators have been embodied in a circular which, as defining the rights of the finder as well as his obligations, deserves the widest publicity. The circular, of which copies may be obtained on application to the Director, British Museum, W.C.1, is as follows: "Objects of *gold or silver* which have been *hidden* in the soil or in buildings and of which the original owner *cannot be traced* are Treasure Trove and by law the property of the Crown. (Unless, as in some rare cases, the 'franchise of Treasure Trove' has been expressly granted to a subject in so far as finds in the particular locality are concerned.) If, however, the finder of such objects reports the find promptly, and it is decided that it is Treasure Trove and therefore the property of the Crown, he will receive its *full market value* if it is retained for the Crown or a museum. If it is not retained, he will receive back the objects themselves with full liberty to do what he likes with them, or, if he wishes it, the British Museum will sell them for him at the best price obtainable. The only way in which a finder can comply with the law and also obtain these advantages is by reporting the find promptly to the proper authority.

"The proper authority is the Coroner for the district in which the find is made, for he is the authority who inquires 'of treasure that is found' and 'who were the finders' (Coroners Act, 1887, section 36.)

"Anyone, therefore, who finds such objects should report the find to the Coroner, either direct or through the local police, or by writing to the Director, British Museum, London, W.C.1, who will communicate with the Coroner.

"Coins and other ancient objects of copper, bronze, or any metal other than gold or silver are *not* Treasure Trove and finds need not be reported to Coroners. But the British Museum is glad to hear of such finds and, if finds are reported to the Director, will in suitable cases arrange for purchase or sale.

"Any further information may be obtained by applying to the Director, British Museum, London, W.C.1."

Symbiosis and Specificity in Lichens

IN an address at the meeting last year of the Swiss Society of Naturalists (Verhandlungen der Schweizerischen Naturforschenden Gesellschaft, 1930) Chodat gives an interesting survey of the history and recent advances in lichenology. As lichens are the only plants which, as a class, are characterised by a dual nature they are the outstanding examples of symbiosis—a term first used by De Bary, by which he did not intend to convey any idea of mutual effect of one symbiont upon the other, either for mutual benefit or the reverse.
